Commercial Paragraphs

The Pittsburgh Testing Laboratory has moved into its new building at the corner of Seventh and Bedford avenues, Pittsburgh, Pennsylvania.

The Universal Vanadium Co. has been incorporated to act as selling agents throughout the world for ferro-vanadium, manufactured by the American Vanadium Co. of Pittsburg. It will act in conjunction with the Vanadium Sales Co. of America. Edward M. McIlvain, 30 Church street, is president.

The Lunkenheimer Co. has recently opened a new branch store at 138 High street, Boston. Wm. W. Beal is in charge.

The name of the Constant-Herzig Co. has been changed to the C. L. Constant Co. The offices of this well known firm of engineers and assayers remains at 42 New street, New York City.

Stephens-Adamson Mfg. Co., of Aurora, Illinois, has opened a branch office at 303 Abington building, Portland, Oregon, under the charge of R. G. Cornell, and will be a large factor in the building of conveying, transmission, and screening machinery in the Northwest. The company has recently completed at Aurora, Illinois, a large new steel shop which will give added facilities. Mr. Cornell was formerly in the company's engineering and later in the sales department in the main office.

American Institute of Mining Engineers

The following itinerary is provisionally announced for the fall meeting, subject to such changes and additions as may be made by the local committee or by the management in charge of transportation:

Saturday, Sept. 30, Lv. Chicago 8 p.m.; Tuesday, Oct. 3, Arr. Grand Canyon 8 a.m.; Wednesday, Oct. 4, Lv. Grand Canyon 7:30 p.m.; Thursday, Oct. 5, Arr. Los Angeles 2:30 p.m., *via* A. T. & S. F. railroad. Sunday, Oct. 8, Lv. Los Angeles 3 a.m.; Sunday, Oct. 8, Arr. Santa Barbara 7 a.m.; Sunday, Oct. 8, Lv. Santa Barbara 11 p.m.; Monday, Oct. 9, Arr. Del Monte 8 a.m.; Tuesday, Oct. 10, Lv. Del Monte 4 a.m.; Tuesday, Oct. 10, Arr. San Francisco 7a.m., *via* Southern Pacific railroad.

Tuesday, Oct. 17, Lv. San Francisco 10:40 a.m., *via* Southern Pacific railroad. Wednesday, Oct. 18, Lv. Ogden 2:30 p.m. *via* Union Pacific railroad. Thursday, Oct. 19, Lv. Omaha 11:30 p.m., C. M. & St. P. railroad; Friday, Oct. 20, Lv. Chicago 1 p.m., *via* Chicago, Milwaukee & St. Paul railroad.

Japan Excursion.—Tuesday, Oct. 17, Lv. San Francisco 1 p.m.; Sunday, Oct. 22, Arr. Honolulu, H. I.; Monday, Oct. 23, Lv. Honolulu, H. I.; Friday, Nov. 3, Arr. Yokohama, Japan, *via* steamship *Manchuria* of the Pacific Mail Steamship Company.

Eighteen-day excursion in Japan, including Tokio; Nikko and Chuzenji district; Tokio, Kamakura, and Hakone; Kioto, Nara, Osaka, Kobe, etc.; Ikuno Silver-Mine; Miyajima, Imperial Steel Works, Yawata, Kiushu, Miike Colliery, Tokio, or Yokohama.

Tuesday, Nov. 21, Lv. Yokohama; Thursday, Nov. 30, Arr. Honolulu; Friday, Dec. 1, Lv. Honolulu; Thursday, Dec. 7, Arr. San Francisco, *via* S.S. *Siberia*, P. M. S. S. Company.

Friday, Dec. 8, Lv. San Francisco 10:40 a.m. *via* S. P. railroad. Saturday, Dec. 9, Lv. Ogden 2:30 p.m. *via* U. P. railroad. Sunday, Dec. 10, Lv. Omaha 11:30 p.m. *via* C. M. & St. P. railroad. Monday, Dec. 11, Arr. Chicago 1 p.m. *via* C. M. & St. P. railroad.

The Goldfield Consolidated Mines Co.

The quarterly report of the general superintendent is as follows:

	January.	February.	March. (approx.).	Total.
Dry tons treated	27,192	23,675	25,814	76,681
Value recovered	$742,980.28	$913,684.43	$1,040,000.00	$2,696,664.71
Operating cost	185,592.48	175,708.80	212,000.00	573,301.28
Construction cost	4,760.85	18,650.59	3,000.00	26,411.44
Total costs	190,353.33	194,359.39	215,000.00	599,712.72
Net profit	552,626.95	719,325.04	825,000.00	2,096,951.99

The cash balance of the company on March 31 was $2,780,989. After paying a dividend of 50c. per share, being the regular quarterly 30c. dividend plus an extra 20c. dividend, the cash balance will be approximately $1,600,000.

TABLE OF CONTENTS

EDITORIAL

EIGHT stenographers, it is said, are employed by Mr. George Graham Rice in his efforts to boom Porcupine. If the supply of white paper lasts, this should secure to everyone a chance to lose money.

POSTAL savings banks are proving popular. At Bisbee, Arizona, $2000 was deposited on the first day the office was open. At Globe and elsewhere in the mining regions the new system affords great convenience.

STATE AID in metallurgical research has been undertaken in Colorado, where an ore-dressing and metallurgical laboratory designed primarily for testing and research rather than instruction, is being built at the School of Mines at Golden.

DUST from portland cement-making plants in California has been making trouble for orange growers, and injunction has been granted against one of the large cement mills in southern California. It is understood that the Cottrell process will be tried, and in many particulars the situation seems especially to favor its success.

OUR attention has been called to an error in our article describing the El Oro steel spud. Mr. W. S. Noyes modestly disclaims credit for the design, which it seems was made by Mr. J. B. Hardy of the Indiana Machine Shop. Fortunately in this, as in other good pieces of work, there is credit enough to go around. The spud, by the way, is attracting much favorable comment from dredging men.

GERMAN coal mine owners are making systematic efforts to increase their foreign trade and are meeting with good success, 58 cargoes having cleared from Rotterdam alone in March. When accessibility and quality of coal are taken into account the field seems even more open to Americans than Germans and the large surplus capacity of our collieries could be thus utilized with great advantage to many local industries.

ALASKAN railways are not under control of the Interstate Commerce Commission and there is no local body corresponding to a State Commission. When shippers desired to object to rates over the White Pass & Yukon route, Canadian authorities were the only ones competent to act. Attention has been called to the matter at Washington and it is probable that the authority of the Interstate Commerce Commission will be extended.

ARMY MEDICAL OFFICERS have good reason to feel proud of their record in connection with the mobilization of United States troops this year. A division of 18,000 men has now been in the field over two months, during which time there has been much rain and bad weather, and yet the percentage of men on the sick list is less than before the men were mobilized. The contrast with conditions in 1898 is inspiring. Incidentally, mining engineers, who must so often be responsible for the health of numerous subordinates, would do well to study thoroughly the methods and results of the army doctors.

ENGLISH is a language having many mutations. Our British cousins always 'amalgamate' companies when in the United States they would be 'consolidated.' Similar differences give point to the announcement in a shop window on the Rue de Rivoli: "English spoken and American understood." A friend in Arizona sends the following as an example of English as sometimes written by an earnest aspirant for American citizenship: "Wey hat too houst 10 cars of wast of the track be for wey could stort on the ore it was 20 minnets too nine befor wey get cleant oup."

AUTOMOBILE extravagance has been charged with many of the ills of society lately, but the latest is the well-attested fact that in the last year delivery of mining machinery on time became impossible because of the demand for mechanics in the automobile plants. One manufacturer employing ordinarily 1800 men was only able to hold an average of 1400 through the season. The profits in automobile-making are so large as to permit payment of wages impossible in the manufacture of standard articles, and serious losses have already resulted.

GLYCERINE is an essential constituent of the high explosives used in mining. In the past the supply has been obtained as a by-product of soap and candle-making, but with the increase in the use of nitro-glycerine and changes in methods of making candles, a serious shortage of glycerine impends. Mr. W. Cullen recently called attention to the situation at a meeting of the Chemical, Metallurgical & Mining Society of South Africa. Unless new sources of supply or an acceptable substitute is found, mine managers must be prepared to pay high prices for explosives. Experimental work should be encouraged. In the meantime urge the increased use of soap and discourage war.

THE Governor of California has not yet announced his choice among candidates for the position of State Mineralogist. The post is an important one and should be filled promptly. There are several men available who would serve in this place acceptably. The last name suggested is that of Mr. F. J. H. Merrill of Los Angeles. Mr. Merrill is eminently qualified for the position. His administration as State Geologist of New York was notable for the high character of the work done by the department while under his control, and there is no doubt that he would fill the position in a way that would make the office what it ought to be—a powerful agent for wise conservation and economical development of the mineral resources of the State. We are sure the Governor desires to appoint a qualified man and we hope the matter may not be longer delayed.

CONSERVATIONISTS are greatly pleased at the decision of the United States Supreme Court relative to the authority of the United States over the public lands. It certainly gives a broad foundation for a conservation policy on the part of the National Government; this places on Congress the responsibility of prompt action. There is a general impression in the East to the effect that the people of the West do not favor Federal control of the water-power sites, or of the coal, oil, or phosphate lands. We would say rather that Westerners object to the withdrawal of these lands and failure to enact any legislation under which they can be utilized. This is perhaps only a temporary incident in the development of the conservation policy, but it is a cause of much irritation. Coupled with this has been the fact that in making withdrawals rights previously acquired have not always been scrupulously respected. This properly offends a native sense of justice. If, however, Congress will offer the people a definite and workable plan, permitting continued development of the lands in controversy, we believe Western sentiment will be found surprisingly favorable. It should be remembered that under present conditions proceeds from the sale of public land are required by law to be spent in the West, and the land once in private ownership becomes locally taxable. It would be unjust to permanently hold free from all local taxation any large part of any State, Eastern or Western, unless some compensation in revenue be provided. We do not believe this is contemplated, and within the suggested limits there is ample room for building a system that will permit at once, proper control, suitable local revenue, and economical development.

CORDOVA has become the centre of interest since its citizens have been giving a realistic revival of the historic 'Boston tea party.' Evidently Cordovans take their United States history seriously. We will confess at once that our sympathies are with them. To stand idly by with your local coalfields securely locked up, and watch the unloading of cargo after cargo of foreign coal, is as exasperating as the situation is unjust. Paying the fiddler may prove distressing, but the participants in the venture will, at least, have the comfort of having acted, and, incidentally, of having thoroughly impressed their view-point on all the world. That Alaskan coalfields are still undeveloped is due to nothing less than a break-down in government. The famous and thoroughly complicated Cunningham case has just been argued at Washington and a settlement is expected within three weeks. The new Secretary of Interior is devoting himself to the Alaskan muddle and, with neither prejudice nor disposition to dodge responsibility, is endeavoring to get at the facts and the law. We have no notion what his decision will be, but we have great confidence that it will be right; and it should settle the matter. It must be followed promptly by constructive work on the part of Congress. Already a year's time has been lost, the matter has been thoroughly discussed, and the needs of the situation are acute. Less attention to the effect on the next presidential election, and more to that on the future of Alaska, is needed at Washington.

Federal Aid for Mining Schools

A bill has been introduced at Washington by Mr. M. D. Foster, chairman of the Committee on Mines and Mining, of the House of Representatives, proposing to extend to State schools of mining and metallurgy substantially the same aid now given to agricultural colleges. Specifically the bill proposes an initial appropriation of $5000 per year to each State, with an increase annually of $5000 until $25,000 per annum is being appropriated. The money can only be used for instruction, research, and experiment, but with that limitation the terms are broad and funds expended under them would be certain to accomplish much good. There is some slight difference of opinion among educators and public men as to whether the United States Government does well to take up the work of instruction, and there are those who hold that it should be left to the States. There is no disagreement, however, as to the propriety of the Nation using its resources to stimulate research and experiment designed to enable more economical development of material and to promote safety. Neither can there be maintained any good argument why in distribution of benefits the miner should be discriminated against in favor of the farmer. The bill Mr. Foster has introduced is well drawn and details have evidently been carefully considered. The object he has in view has been before Congress often enough for intelligent action. Western miners are especially concerned, since it is in the West that the

work proposed most needs doing, at the same time that the facilities are most inadequate. The House Committee on Mines and Mining gave last year a notable exhibition of what a few determined men, among whom was Mr. Foster, can accomplish even with a moribund institution. They went far to make it, as it should be, one of the most important committees at Washington. The bill now proposed, H. R. 6304, deserves support, and the active cooperation of mining men is urged.

Wanted,—Mines

Probably more money is now available for investment in mines than at any time in recent years—and the mines are not being found. Those that come to notice, even many but incompletely developed, are promptly financed if the owners are at all reasonable in their attitude. Within a year an expensive examination of a California gold mine was made, where the ore averaged only $2.60 per ton in value. The mine was rejected, not because of the low value of the ore, but because the quantity proved did not warrant the investment. The orebodies found at Porcupine passed promptly into the hands of experienced and capable men amply prepared to furnish all the money needed to develop them on the largest scale, and there is money waiting for anything else that shows equal promise. The case is all the more striking since even now relatively little ore has been developed at Porcupine, if the word be used in the strictest engineering sense. Men having money and experience were, however, at once attracted to the camp and were willing to buy upon terms that involved substantial risk on their part as well as profit to the owners. Men accustomed to investing large sums of money are now willing, as seldom before, to go into metal mining; but, and this spells the difference, they have learned to value expert assistance and they know the difference between a mine and a hole in the ground. The little artificial flurry in Porcupine 'stocks' in New York, and the promptness with which it subsided, indicates that even the general public is disposed now to discriminate between investment, and buying capitalized blue sky and adjectives. There are constantly in San Francisco, and the same thing is true at other centres of mining, representatives of a number of financial groups anxious and willing to buy any mine that is likely to prove profitable. If one has a mine of real value it is not necessary to reach capital through a long string of hungry promoters. Anyone who knows what he has and is prepared to talk business can get a respectful hearing. These facts are thoroughly well known among engineers. We state them for the benefit of the general public and perhaps, for the small mine-owner who is too busy on his claim to visit the city often.

It is an encouraging sign of the times that substantial business men of large resources are prepared to invest in metal mines on terms fair to all concerned, including the promoter and the minor stockholder. It is to be hoped that their experience may justify a continuance of this attitude. Making mining less of a game for gamblers, and more a business for investors, is worth while. We would not, however, lose sight of the fact that in legitimate mining there is a stage where speculation is a large element. This, though, we believe is properly in the development of prospects rather than the manipulation of shares in companies operating producing mines. A prospect is always uncertain. To discover it in the first place, and to develop it in the second, calls for skill, experience, and money. Much of the first two, and, relatively, little of the third, are needed. This is the part of mining that attracts the man who has little capital but abundant nerve and optimism. Of the whole number of prospects found, few make good mines; but a mine once developed can be promptly converted into cash at a very large profit on the original investment. A prospector may work all his life and never discover anything of value. He may become wealthy in a few months. Surely this affords a sufficiently wide field for any legitimate desire to speculate.

It is none too easy to find even a good prospect. Most of the rich ore-shoots that outcrop at the surface and pay 'from the grass roots down' have already been staked. Great portions of the world have been thoroughly prospected so far as this stage of the work is concerned. Not that similar ore-shoots will not still be found in the old and 'thoroughly prospected' country—indeed, experience at Cripple Creek, Goldfield, National, and elsewhere, urges to the contrary—but in the main, prospectors must expect either to go into country till now inaccessible or to spend more in testing each outcrop in depth. Until the automobile was developed, much desert country was practically inaccessible and rich ore outcropped at the surface without attracting attention. In the Northwestern States, in British Columbia, and in Alaska, there are doubtless many bodies of ore as valuable as any yet found on the Mother Lode, in the Coeur d'Alene, at Nelson, or at Juneau; but the country is heavily covered with forest and underbrush, and many parts are only accessible with great expense and difficulty. Evidently discovery of new districts here must wait on lucky chance or follow much more difficult and persistent search than led to the finding of mines now worked. In Ontario and adjacent provinces there are thousands of square miles covered with forest or muskeg. The country is almost wholly unprospected. Rock outcrops are few and trenching is necessary. A knowledge of geology is extremely helpful if not essential. Cobalt and Porcupine point to the possibilities of the area and a wide expanse awaits the prospector.

Modern prospecting is a peculiarly suitable field for the organization of limited partnerships or small 'syndicates,' to use a large and pleasing word for a modest venture. The men going into it should recognize the speculative nature of the business and should choose their field agent with care. This done, they should be hopeful and persistent. When a suitable claim is found, attention should be concentrated on finding ore. There is no need to worry over metallurgical difficulties or treatment charges; if the ore is found it can be sold at a profit to some one else who will shoulder those worries. Find ore, that is the first essential; do not gouge it out so that nothing is left but the shell, that is the second. It is a mistake to waste good ore by mining and selling it at the high costs always incident to prospecting operations. Find the ore, take your profits and find more ore, and you will soon cease to worry over the increased cost of living. Show faith in your prospect. If you can not do that, stay out of the business, but if you go into the game play it fairly. Not long ago our attention was called to a company financed and promoted by attorneys and bankers and engaged in selling stock to the general public. A report by a reputable engineer stated his belief that expenditure of $25,000 would result in developing several hundred thousand dollars worth of ore. The amount needed was by no means beyond the resources of the group handling the property. Yet they were asking the public to furnish it. Either, apparently, they had no faith in the engineer and the property, or they wanted to have their cake and eat it too. There have been too many organizations designed on the comfortable basis of the public supplying all the money and receiving but an exceedingly diminutive share of the profit. Good properties in good hands are not so financed, and if either of these essentials is lacking, any proposal for investing is likely to prove unprofitable.

Operation of the Goldfield Consolidated Mill

By J. W. Hutchinson

(Continued from page 616.)

CONCENTRATION

The third aisle of the mill is the main concentrator floor, containing 30 8-ft. Callow tanks, and 60 primary and 16 secondary concentrators (all No. 3 Deister slimers). The concentrators were put in after a competitive test on this ore with the suspended vanner; the Deister No. 3 machine winning by a wide margin. Each machine has the capacity, when followed by secondary concentrators in the ratio of 1:5, of handling 11 tons of dry slime, 80% of which will pass a 200-mesh screen and all of which will pass a 100-mesh, and each will concentrate therefrom 72% of the gold in the ore into 1000 lb. of concentrate. From this, 20% of the gold is recovered by amalgamation, leaving 52% to be recovered by further treatment of the concentrate. When the facts are taken into consideration, that the ore has been slimed before any of the concentrate has been removed, that 80% of the material recovered is −200-mesh, and that the ore can not be classed as a concentrating ore, the performance seems remarkable. Repeated monthly tests on a general sample of the tailing from the cyanide plant fail to show any appreciable gold recoverable by concentration. When the capacity of the plant was increased, 18 additional tables were placed on the regrinding floor, and 6 on the secondary floor. As stated, the tables on the regrinding floor take their feed from the spitzkasten, this feed assays 20% higher than the feed on the main floor. For this reason, the middling from the 18 upper tables is re-concentrated on the main floor and the tailing from the upper floor mixed with middling from the 60 primary tables.

Although 30 Callow tanks were placed on the main floor and were used for dewatering when the plant crushed 600 tons, at the present only 16 are in commission, since less water is now used for crushing. The Deister machine operates more satisfactorily on a pulp containing 3 to 3½ parts water. They are driven at 300 strokes per minute through $^{7}/_{16}$ in. and require 0.73 hp. each to operate. One man per shift operates the 60 primary and 16 secondary tables; one man with a helper keeps all the machines in repair. This work includes all mechanical up-keep, as well as cleaning floors, machines, and pulp-thickeners. The helper brushes the mineral edge of each table every morning with a dilute HCl to remove precipitated salts. Each deck is brushed thoroughly every 60 days. No deck renewals have yet been necessary.

The concentrate from all floors, approximately 5½% by weight of the ore milled, gravitates to the concentrate-treatment plant and will be discussed later. Middling from the primary tables, amounting to 15% by weight, is re-concentrated without further regrinding on the 16 secondary tables. Reference to the flow-sheet will show the disposition made of each product. The cost for all renewals for 94 tables, including head motions, deck, riffles, etc., has averaged $150 per month for twelve months, or at the rate of $1.60 per table per month, or 0.6c. per ton milled. The labor for repairs and maintenance has been approximately $3 per table per month, or 1.2c. per ton milled, which includes everything incident to keeping the tables in first-class operating condition. The following table shows the total cost of concentrating, including the above items of repair:

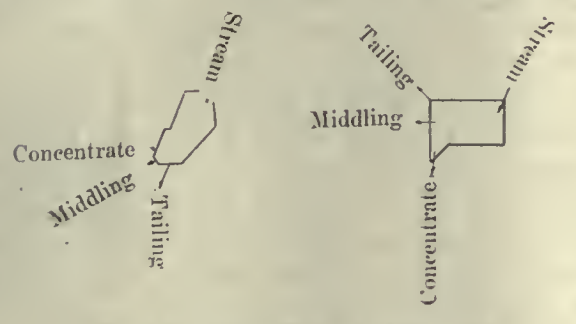
Year	1911	1910	1909
Tonnage	850	850	600
	Cents.	Cents.	Cents.
Labor	3.5	4.0	4.0
Supplies	0.5	0.4	0.4
Power	1.5	1.5	1.8
Total	5.5	5.9	6.2

As pulps are being conveyed here with more variety in size of solids and degree of dilution than in the gold mills of this country or elsewhere, it is hoped the following table will prove of interest:

Product.	Dilution	Width of launder	Height of launder	Grade of launder	Dry tons handled in 24 hr.	Conveying pulp.
		In.	In.	In. per ft.	Tons.	
4-mesh from batteries	4:1	8	8	1¾	255	From 30 stamps to spitzkasten.
12-mesh from batteries	6.5:1	8	8	⅝	200	(1909) from 30 stamps to 8-ft. cone.
−4 mesh to Chileans	3.3:1	8	8	1⅛	400	From spitzkasten to three 6-ft. Chilean mills.
−30 mesh from Chileans	3.3:1	8	8	⅝	400	From three 6-ft. Chilean mills to boot of B. & B. elevator.
Tube-mill discharge, 50% −200 mesh	1.5:1	6	5	1¾	100	From one 5 by 22-ft. tube-mill to boot of B. & B. elevator.
Mixture of tube-mill and Chilean products	2.6:1	8	8	¾	700	From three 5 by 22-ft. tube-mills and three 6-ft. Chilean mills to 8-ft. cone.
Mixture of tube-mill and Chilean products	2:1	6	5	1⅛	200	Feed to one Dorr classifier.
Final product from tube-mills	3:1	5½	8	⅜	330	Feed to 30 No. 3 Deister slimers.
Product from Callow tanks	3:1	3½	3½	⅞	22	Feed to 2 No. 3 Deister slimers.
Concentrate	9:1	3	3	$1^{1}/_{16}$	3.5	From 6 No. 3 Deister slimers to main launder.
Middling	3:1	3	3	¾	10	From 6 No. 3 Deister slimers to main launder.
Tailing	5:1	5	5	¾	52½	From 6 No. 3 Deister slimers to main launder.
Concentrate	9:1	4	10	¾	50	Main launder to concentrating plant.
Tailing	5:1	10½	10½	$^{3}/_{16}$	800	From 100 stamps.
Clear water		18	14	⅛	4000	Clear water overflow from 800 tons.

NEUTRALIZING AND DEWATERING

The lime-mixing plant is situated about 200 ft. from the mill proper and consists of storage bins (capacity 120 tons) into which the lime from the railroad cars is shoveled. Lime from these bins is slacked and dumped into two 4-ft. Wheeler pans, from which the mullers have been removed. These pans act simply as stirrers and deliver a continuous stream of milk of lime, which is laundered to the mill, with branch launders to the dewatering tanks, Pachuca agitators, and concentrate-treatment plant. The bulk of the lime consumed is added to the main launder conveying the table tailing to the dewaterers. No lime is added at the battery, and for this reason there is not the serious trouble with concentrator decks noticeable at most cyanide plants. The



FLOW OF MATERIAL OVER DEISTER TABLES.

lime for neutralizing is so regulated that the overflow water from the dewaterers titrates 0.4 to 0.5 lb. CaO per ton of water. This mill-water gravitates through two clarifying tanks to mill-water sump-tank, from which it is elevated by means of two 10 by 12 Aldrich pumps to the mill-water supply tank behind the stamps. The water leaving the batteries is a trace acid to phenol, which acidity has increased to 0.2 when the pulp reaches the concentrators. The ferrous salts generated during crushing are neutralized and oxidized en route to the dewaterers. The 16 dewatering tanks, 29 ft. 6 in. by 12 ft., with 16° false cones, are arranged in two aisles of 8 tanks with 7 ft. difference in elevation. The total capacity of the dewaterers is 96,000 cu. ft., equivalent to 120 cu. ft. per ton of ore, or 20 cu. ft. per ton of pulp. Each tank is equipped with a central well for the inflow of pulp, and peripheral launders and pipe decanters for handling the clear water. The helper in the cyanide plant regulates the lime and settlers, decants and transfers the charges. The cost of these operations is as follows:

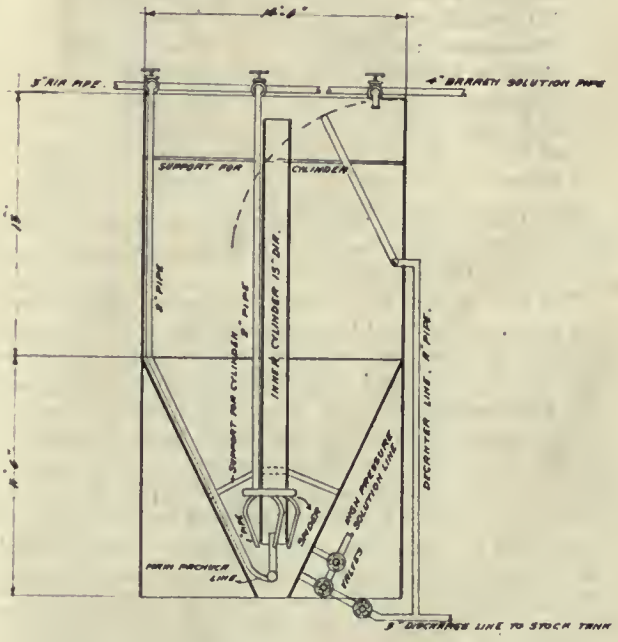
	Neutralizing, cents.	Dewatering, cents.
Labor	0.6	1.4
Supplies	4.1	4.1
Power	0.1	0.1
Total	4.8	5.6

CYANIDATION

From the dewaterers the pulp, containing 40% water, is pumped to a battery of ten 15 by 45-ft. Pachuca agitators, arranged in series, and is diluted to 1½:1 (Sp. G., 1.35) with solution from the wash-solution tank (No. 3 above) in the Butters filter system. The solution is increased to 1.2 lb. KCN per ton and the alkalinity 0.5 lb. in terms of CaO, and maintained at these strengths for 26 hours. Lead acetate, to the amount of ¼ lb., is added at the beginning of treatment and again in tanks 4 and 8 of the series. This seems unusual for gold ores, but the decomposition of the complex sulphides in the Goldfield Consolidated Mines Co.'s ore makes it necessary. All attempts to reduce the amount have resulted disastrously. Various oxidizing agents, together with bromo-cyanide, have been tested on a working scale without commercial success. The bromo-cyanide gave increased extraction, but the cost was prohibitive, except on high-grade ore. As stated, concentration tests on the tailing are made on a general monthly sample, but the loss is not in recoverable concentrate.

There is one feature which is most interesting. The assay value of the −200 product in the tailing is considerably higher, nearly 30%, in fact, than the product remaining on 200 and 150-mesh screens. This is true in both the mill and concentrate plant and is doubtless due to the presence of very brittle and insoluble alloys of gold. A picked sample of the higher-grade ore supplied to the mill gave by analysis the following percentages of elements which tend to confirm this theory: Bismuth, 0.25; antimony, 0.055; tellurium, 0.025; selenium, 0.050.

In the agitators approximately 80% of the value of the ore after concentrating is dissolved. Previous to connecting the tanks in series they were operated as 4 batteries, two of 3 and two of 2 tanks. At a gravity of 1.35, with a loss of 4 hours for transferring, the average period of agitation was 23 hours. After the publication of M. H. Kurylas' article on the results of continuous agitation at Esperanza, I wrote the management of that property asking for additional information, which was given. Using Mr. Kurylas' sketch, the Pachuca tanks were connected in series by means of 8-in. pipe connections, and experiments begun. These were not favorable to continuous agitation, and for six months thereafter the tanks were worked intermittently. The failure of the system was not explained until recently. After a new compressor with much more capacity than those previously used for agitating was put in, the tanks were again connected in series and with marked success. The only reason known here for the failure at first is that uniform agitation throughout the series is most essential. With the inadequate amount of air at



PACHUCA AGITATOR FOR CONCENTRATE TREATMENT.

that time, this could not be maintained, and the tailing, gravitating from the series to the filters, had not received uniform treatment. The following assays will give an idea of the first and second trials.

	First Trial.			*Present Operation.*		
		Oz. Au.			Oz. Au.	
	Gravity.	Pulp.	Sol.	Gravity.	Pulp.	Sol.
Heads	...	0.44	...	...	0.62	...
Agitator No. 2	1.36	0.17	0.17	1.35	0.31	0.21
" No. 4	1.36	0.16	0.17	1.34	0.26	0.256
" No. 6	1.34	0.16	0.18	1.33½	0.20	0.30
" No. 8	1.33	0.14	0.193	1.33	0.14	0.328
" No. 10	1.33	0.12	0.20	1.32	0.10	0.348
Filter Tailing	...	0.10	...	...	0.08½	...

The lighter gravity in the last tanks of the series is accounted for by the addition of solution for dissolving chemicals. The screen tests on the various tanks is as uniform as could be expected. There are so many different

kinds of ore being fed to the mill, that it is impossible to make a definite comparison of the two methods of treatment, as the ore varies within wide limits during a week's run. The continuous system during the first run was alternated weekly with the intermittent three times, with an apparent increase in tailing loss of 30%. The present operation shows a decrease of nearly the same amount, but on a higher grade of ore. The following analysis of the solution before precipitation shows some of the difficulties encountered in the treatment:

Analysis of Cyanide Solution at G. C. M. Co. by Von Schultz & Low.

(The percentages refer to the weight of the solution. Total solids by evaporation, 0.3932%. Sp. gr. solution at 70°F., 1.002.)

	Per cent.
Silica	0.00198
Ferric oxide	0.00014
Alumina	0.00020
Manganese	Trace
Lead	Trace (faint)
Bismuth	Trace (faint)
Cadmium	Trace (doubtful)
Copper	0.03686
Arsenic	0.00010
Antimony	0.00014
Nickel	0.00010
Cobalt	0.00020
Zinc	0.00330
Selenium	None
Calcium oxide	0.02837
Magnesium oxide	0.00014
Phosphorus pentoxide	Faint trace
Sulphur trioxide	0.03282
Chlorine	0.03260
Tellurium	0.00008
Gold	0.185 (oz. Au)
Silver	0.068 (oz. Ag)

The total sulphur was determined as sulphur trioxide, and no attempt was made to determine the form of combination of the elements found.

The cost of cyaniding, which, in the method of accounting employed at the plant, is really the cost of agitating, includes all chemicals necessary for the dissolution of gold, and all labor connected with the operation of tanks, pumps, and compressors, is given below. Naturally the cost has varied considerably during the three years operation, due to the increasing cyanide consumption. The mechanical cost is practically constant. Approximately 75 cu. ft. of free air per minute is required for each tank of 85 dry tons, equivalent to 6 hp. per tank. Power per ton agitated is 2c. Maintenance and repairs for tanks, compressors, pumps, and pipe-lines is less than one cent per ton agitated. The total cost, including all the above items of chemicals and repairs, is as follows:

Year	1911	1910	1909
Tons	850	850	600
	Cents.	Cents.	Cents.
Labor	2.8	2.6	2.8
Supplies	56.6	51.0	40.3
Power	2.4	2.5	3.2
Total	61.8	56.1	46.3

It may be well to state here, in order to correct erroneous impressions given in articles on cyanidation of the low-grade surface ores at Goldfield in mills other than those of the Goldfield Consolidated Mines Co., that it is a characteristic of the sulphide ores of the district to increase in refractory elements with the increase in value. One notable shipment of high-grade ore contained nearly 2.5% tellurium with a gold content approximating 2%. With depth the baseness of the ore naturally increases. It has been demonstrated here to the satisfaction of all interested, that the lower-grade ore is more amenable to treatment by cyaniding than the higher-grade ores, and that the percentage of gold extracted does not necessarily increase with the increase in value. This is the inference made in some recent articles commenting on the extraction of one of the local mills, operating on $12 upper-level ore. It is stated that this mill makes a saving of 93% on such ore, which approximates the saving made at the Consolidated mill on $30 ore. It is interesting to note that immediately after the fire of 1910, when the higher-grade ore from the deeper levels was shipped to smelters, and the mill heads lowered to something like twice the value of those at the mill referred to, the extraction at the Goldfield Consolidated mill averaged 96%. As soon as normal operations were resumed with the mill treating all the deep-level ore, with consequently increased value in the feed, the percentage recovered dropped to 94½, which was the average for the year of 1910. Attention may be called to the performance of the old Combination mill, which for crudeness of design and lack of conveniences rivaled the plants in question. In this mill, which treated the upper-level ores, and consequently those least refractory, an average extraction of 95% was maintained. It has been the policy of the Consolidated company to include in the cost in its monthly and annual reports the residues from the concentrate treatment plant which could not be shipped at a profit, with the tailing losses at the mill. As a consequence the published report of recoveries has not been a statement of the metallurgical efficiency, but more nearly the statement of the percentage of value applicable to expenses and profits. Therefore, the greater metallurgical efficiency in the concentrate plant resulted in a lower reported extraction in the mill.

(To be Continued)

Filling Mine Workings

By Charles Enzian

The tailing from the screens preparing the smallest coal for market, or particularly for boiler fuel purposes, called the 'culm', is utilized in the anthracite district of Pennsylvania for mine filling. This culm is taken into the mines by means of bore-holes or pipe-lines in the shaft or slope, in mixtures containing about 90% water, and deposited into worked-out chambers, being confined by means of suitable dams and batteries. The water drains off and the culm remains as residue, which in the process of depositing and draining generates considerable heat due to the pyrite particles present, and this, in combination with calcareous or carbonaceous shale finely ground and held in suspension by the water, forms a binder. The aggregate becomes quite firm and will stand unsupported after some time and thus sustain considerable weight. This enables second mining to the extent of from 25 to 35% of remaining solid ground. The new opening is then filled and allowed to settle into stability, and, depending largely upon whether or not the surface is valuably improved, and assuming that a risk of subsidence would be discreet, an additional or third mining may be undertaken, leaving at least 50% of the remaining solid as permanent support and the filled area to give vertical and lateral support.

To illustrate: Assuming that the first mining was so conducted as to leave 60-ft. pillars solid, the chambers being worked 20 ft. wide; this would leave a 'remaining solid' of about 60 ft.; upon the second mining, a 15-ft. slice is taken, representing 25% of the remaining solid, or a total extraction of 44%. After filling again, another slice of 20 ft. is taken, or 44% of the remaining solid, thus giving a total extraction of 70% of original solid—an ultimate mining impracticable without the method of refilling or 'flushing' as it is termed. The flushing may be with other than vein material. A common practice at the present time is to crush all refuse material from breakers, boiler plants, and rock banks, and flush into the mines. Flushing should be done systematically and scientifically; keeping in mind the preservation of roads and air courses. This necessitates building dams at the foot or entrance of each chamber, also a drainage or overflow through the entire chamber length for the escape of accumulated water, thus relieving the dams from water pressure.—*The Black Diamond.*

The Bugbear of Gold

By Charles Sewell Thomas, Jr.

Much has been said concerning the enormous gold production of the world, how it has advanced since 1880, like a great financial cyclone threatening the destruction of all credit, how it will continue to increase abnormally, and how it will eventually swamp the earth and all its industries, reducing values to chaos. It is said that the use of gold in the arts is limited—almost negligible compared to its use as a medium of exchange, that its value exists only in the mind of man. From this it appears that, should the quantity of gold become so great as to render it no longer of value as a basis of values, there will be no use for it. Enormous quantities of gold are said to exist in sea water. Untold millions of ounces of it are 'known' to exist in the clays around Philadalphia, huge deposits are spoken of, with bated breath or described with reluctant pens, in other localities. New processes whereby deposits less than fifty cents per ton in value can be profitably worked are coming to the fore—so it is said—processes that experimenters fear to tell about on account of the great harm that would result should they be utilized. So much has been said that it may be worth while to consider the matter from the miner's point of view. A consideration of the physical and chemical properties of gold, and of its occurrence in nature, will help to an understanding of the truth about the solubility of gold in sea water, of the possibility of it being held in suspension in sea water, and of the possibility of its existence in clay banks.

Gold's specific gravity is very high, 19.29. Some physicists have obtained a specific gravity as high as 20.72 by precipitation from special solutions. It is more malleable and more ductile than any known metal; leaves not more than one three hundred thousandth of an inch in thickness can be obtained by beating it. Its hardness as compared to the diamond is as 979 is to 3010. When pure, it has a tenacity of 7 tons to the square inch. Its electrical conductivity is only exceeded by that of silver and copper. It is soluble in free chlorine, in mixtures containing chlorine and bromine, in the hyposulphites of calcium, sodium, potassium, and magnesium in the presence of an oxidizing agent, in selenic acid, and in the alkaline cyanides. It is also soluble in sulphuric acid when electrolyzed, but is almost immediately precipitated by the liberated hydrogen. It is insoluble in water except under enormous pressure. With mercury, gold forms an amalgam of variable composition from which it may be freed by distillation. Advantage is taken of these properties in the extraction of gold from its ores by cyanidation, amalgamation, and mechanical concentration. In nature gold is almost always found in its native, or uncombined, state. A great deal of it occurs in combination with tellurium, the principal localities being Cripple Creek and Western Australia. Very rare compounds of gold with palladium, rhodium, and bismuth have been observed, but they are absolutely negligible as a source of supply. With few exceptions gold exists only in the volcanic or igneous crystalline rocks. Sceptics, contemptuous of the knowledge of engineers and geologists when the latter attempt to draw the line between auriferous and non-auriferous country by making use of the knowledge gained from countless districts, often say that "gold is where you find it." That is undoubtedly true. Anything is where you find it. But there exist many conditions, that are well known and without exception, under which gold cannot be found.

It has been said by many that gold exists in sea water. This hypothesis has been upheld by several reputable chemists, chief among them being J. R. Don, Henry Wurtz, and Luther Wagoner. The largest quantity found, however, was 16 milligrams in a metric ton, or, $0.0097 per metric ton in value. Of all the chemists attempting to isolate gold from sea water only Mr. Wagoner succeeded, and then only by the most painstaking and expensive methods of analysis.

Gold cannot be held in solution except in the form of a chloride, a cyanide, or a hyposulphite. In analyses of sea water cyanogen is not found. No free chlorine, the only solvent of gold, exists and there is only enough combined chlorine to satisfy the chemical requirements of the alkaline earths found. Therefore it may safely be assumed that the gold is combined in such extremely minute quantities that the presence of its solvents makes no appreciable difference in the regular analysis. If there were any greater quantity than about 15 milligrams per metric ton (12 milligrams per cubic yard) the presence of its solvents would be quite easily detected. And surely no one would go so far as to assert that a metal of the high specific gravity of gold could be held in suspension throughout countless centuries in any but the most minute quantities. It has been asserted that sea water carries 5c. in gold per cubic yard. This would be about 6½c. per metric ton. The only printed record I can find of any such quantity as this was in the literature of the Electroyltic Marine Salts Co. of Maine—a most notorious 'wild cat' swindle.

Again, suppose gold does exist in sea water to the amount of five cents per cubic yard. Its value decreases when the matter is examined from an operating standpoint. How many cents worth of chemicals per cubic yard of sea water would be necessary to obtain the proper conditions for gold precipitation? Certainly more than five. If to this be added depreciation on an immense plant, the idea becomes absurd. Suppose concentration by evaporation be tried. If natural evaporation is employed there must be more outlay for plant. If artificial evaporation be attempted the cost of fuel will add its quota to the cost of operation. Again where should the waste water be run so that the ocean, in time, may not be diluted? From a study of the literature on the subject I am of the opinion that the most painstaking analyses of sea water will not reveal an average of over $0.005 per metric ton, or $0.004 per cubic yard. It is fairly obvious that even with a great falling off in the prices of commodities, and consequent decrease in operating costs, the economical extraction of gold by any conceivable metallurgical process is impossible. We need not fear the possible demonetization of gold through overproduction from sea water.

Consider the case of the clay bank under Philadalphia. This has been said to carry 30c. per ton in gold. The only dimension of this bank that was given was a length of forty miles. Is it to be assumed to have width and thickness, or not? To have arrived at the value of this clay, assays of representative samples must have been made. The vital questions in valuing this deposit are: how were the samples taken, how were they spaced, and how many of them were there? I will venture to say that the valuation of this forty-mile clay deposit was made on not more assays than can be counted on the fingers of two hands. Suppose the clay to be a mile wide and a few feet thick. It is a matter of simple arithmetic to divide it into squares, 100 ft. on a side, and determine how many samples it would require to properly valuate it, taking samples 10 ft. apart on the lines of these squares. The job of taking these samples would cover a long period of years if properly done. The value of 30c. per ton for this clay may be taken as unwarranted until proved in some such manner as outlined. Clays are alluvial, lacustrine, or glacial deposits; generally they were deposited in some inland lake; occasionally along a seashore. Why—if sandstone, limestone, etc., deposited by heavily impregnated seas, do not generally contain gold originally laid down with them, and then only in most minute quantities—should clay be favored with the precious metal? Gold must come from some place, and the chance for it to be brought in and deposited in any rock where it does not originally exist must be given it by some dynamic disturbance that will open fissures. The entire clay bank referred to above would have had to be fissured in order to allow gold-bearing solutions to deposit their contents, for one of the properties of clay is its imperviousness to liquids.

In an endeavor to throw light on ore genesis, J. R. Don

some years ago made an elaborate series of experiments with many classes of rock, assaying all of them for gold. In the course of his work he found that several sedimentary rocks contained small quantities of gold, but only discovered this to be the case in rocks in the immediate vicinity of ore deposits. To narrow the field still further, it may be stated that in fully 90% of the cases where he found gold in the sedimentaries, it occurred in slates containing pyrite. Thus it is possible that the gold found was introduced by or after metamorphism, which made the slates, and not as an original constituent of the rock. The average quantity he found under these most favorable circumstances was 2.27 grains per long ton, or $0.11. In most cases, even near ore deposits, he got nothing at all of value from the sedimentaries, and in practically all cases at any distance from the ore deposits he got no gold. It is a generally held hypothesis that at some time in the past all beds of limestone and shale were deposited in inland seas; seas more heavily impregnated with solids than the present. Yet the largest amount of gold found in clean, unmetamorphosed sedimentaries is 39 milligrams per metric ton, or $0.0236 per metric ton in value. It is reasonable to assume that there was considerable concentration in the deposition of these beds of rock so that the seas from which they came must have contained most minute quantities of gold, if they contained it at all. Now, assuming that this clay bank does contain an average of 30c. per ton, the question of profitable mining and extraction, now and in the future, is of importance. It is necessary to take into account the rise in the prices of commodities and labor. Unless handling can be accomplished without power or labor, the cost of both rising year by year and the purchasing power of gold falling year by year, I fail to see how this great deposit of gold can be mined and treated even with great improvements in metallurgical processes. Mining with steam-shovels, handling material mined, disposal of waste and overburden, crushing and disposing of tailing will all make a charge of over 30c. per ton at present-day costs. The future, with its rise in prices, would increase this.

The rise in the price of commodities is, by many, ascribed to the immense production of gold. This is to be questioned if one takes into consideration that expansion of business has far distanced increase in gold production. If this is not so, why the advance of credit shown by the panic of 1907 so far ahead of the actual gold supply and the subsequent adjustment of business conditions more nearly to the gold supply of the world? In the principal gold-producing districts of the world the value per ton of the ore produced has been gradually falling. The great improvement in mining methods and metallurgical processes have so far kept pace with the fall, that the net profits per ton of ore produced have been fairly well maintained at a constant figure. But the time has come where further improvement will come but slowly, and, eventually, gross yield per ton and cost per ton will meet, and where this occurs further mining must necessarily cease. The following table is of interest in this connection, as it shows the condition of gross yield approaching gross costs. It represents statistics of the Rand Mines in South Africa, at present producing over one-third of the world's gold output each year.

Year.	Recovery per ton.	Cost per ton.	Dividends per ton.
1897	$9.53	$7.10	$2.43
1898	9.91	6.72	3.19
1899*	10.50	8.35	2.15
1903	9.55	6.91	2.64
1904	9.40	6.96	2.44
1905	8.59	6.53	2.06
1906	8.35	6.34	2.01
1907	8.16	6.00	2.16
1908	7.58	5.31	2.27
1909	6.91	4.71	2.20

*1899 to 1903, war period.

Those who prophecy an increase in gold production each year as great as has occurred in the last thirty years are easily answered. Statistics covering the period from 1880 to the present are valueless as a basis for future production prophesies. Thirty years ago the mining industry was in its infancy. Most mining was confined to placer work and to mining large bedded deposits. The placer miner far outnumbered the hard-rock, or lode miner, and about the sum of the knowledge of the metallurgy of gold was that it would amalgamate with mercury and could be so recovered when passed over riffles containing the latter. Today the industry is in its prime and extractions of gold are made at a cost per ton that was impossible thirty years before. The lode miner has far outrun the placer miner. Costs have been reduced to a point where they can hold their own with decrease in value of deposits and increase in prices. This abnormal development is the result of thirty years experimentation. The mining engineer thirty years ago knew little of underground mining or of the economic geology of ore deposits or of genesis of ores. Today he is an expert in the mechanics of breaking and handling material, the chemistry of metals, and the action of water on material of different specific gravity when certain impulses are given it. Mining, metallurgical, and realization costs in most places thirty years ago were such as to make ore worth less than $50 per ton unprofitable. Today in most places, these costs are seldom over $5 per ton. In a nutshell, the period from 1880 to the present represents the growth of the mining industry from a slow dormant state to its present importance. It is the period of maximum development and represents an increase in knowledge and efficiency of several thousand per cent. Hereafter improvements must necessarily proceed much slower, as in any industry that has passed the experimental stage, and the next decade will show a much smaller percentage of increase for the same reason. It will show less increase for another reason. Thirty or forty years ago little was known of the economic possibilities of most of Western America, Alaska, Canada, Mexico, South America, Central America, Australia, and Africa. Today, the unknown area of the world's surface is much less than it was at the beginning of the great rise in the world's gold production. The new fields that will come into prominence in the future will certainly do a little more than balance the ultimate exhaustion of the present fields. Rise in prices can not be attributed to too much gold, whatever else may be the cause. Rather, too little gold may sometime be attributed to rise in prices, if the latter continue to rise as they have in the last decade, for they will ultimately make the exploitation of anything but very high-grade deposits impossible.

Manganiferous Silver Ores

Manganiferous silver ores, according to E. C. Harder of the U. S. Geological Survey, consist of mixtures of manganese and iron oxides with small quantities of silver sulphide and lead carbonate. As a rule, the iron content exceeds the manganese content, but locally the iron is altogether absent. Manganiferous silver ores are divided into three classes, according to their uses: (1) The greater number of such ores is used for their silver and lead content. Manganese and iron content often insures these ores a higher price because of their fluxing value. (2) A second class of manganiferous silver ore is too low in silver and lead to be used as a source for these metals, but is sufficiently high in manganese and iron to be used for the manufacture of ferromanganese and spiegeleisen. (3) There is a third class of ore too low in silver and lead to be used primarily for these metals and two low in iron and manganese to be used for the manufacture of iron-manganese alloys. This ore is sold to the smelters as flux, the iron and manganese becoming waste products, while the silver and lead content is recovered during the smelting. These ores occur in the Rocky Mountain and Great Basin regions, the principal producing locality being Leadville, Colorado. Some of the Leadville ores are used in the manufacture of spiegeleisen. All the other localities produce these ores for fluxing only.

Ruby Mines of Burma

By John L. Cowan

It is regarded by gem experts as not improbable that the 'synthetic process' of manufacturing rubies will render unprofitable the further operation of the great ruby mines of Burma, and bring that ancient industry to a premature close. As yet, however, the British lessees of the ruby mines show no indications of apprehension as to the future. They have expended large sums of money on a drainage adit, designed to relieve the mines of the excessive floods of water that have always impeded operations, and have given serious consideration to a plan for introducing American hydraulic-mining methods to enable them to work the vast hillside expanses bordering the valleys, in which rubies are found in quantities insufficient to justify the mining methods employed in the valleys. Whether the mines are doomed to speedy oblivion, or destined to long retain their place among the world's greatest gem mines, these notes compiled from material supplied by the Burma Ruby Mines, Ltd., of London, England (with permission to reproduce the accompanying cuts) may not be uninteresting.

Shwebontha Ruby Mine.

The Burma ruby mines have been worked for at least 300 years, but little is known concerning their history. In 1597 the ruby-producing villages of Mogok and Kyat-pyin were traded by the Shan ruler to the king of Burma, who gave in exchange an important town on the Irrawaddy river. From that time until 1885, the ruby mines were claimed as the personal possessions of the Burmese monarch. Foreigners were forbidden to visit the neighborhood, and native miners were permitted to search for rubies only on condition that any stone found exceeding a specified size must be turned over to the Crown. The result might easily have been foreseen. Unless an emissary of the king happened to be on the spot when a gem of exceptional size was discovered, it was promptly broken into fragments. Its value was reduced to a fraction of what it was originally, but the finder received the benefit.

In 1885 Upper Burma was annexed to Great Britain, and not long afterward the ruby mines were leased by the Crown to British subjects. In 1889 the lease was taken over by the Burma Ruby Mines, Ltd., with a capital of £300,000; and from that time dates the modern exploitation of the world's greatest ruby mines. It was felt that it would be both unjust and impolitic to dispossess the native miners, who, like their ancestors, had been mining rubies under the restrictions imposed by the Burmese monarch for generations. So these were permitted to continue at work, on terms more advantageous than they had enjoyed under the native regime. Each native operator is allowed to employ as many men as he pleases, paying to the company a fee of 20 rupees per month, and disposing of the stones found as he wishes. The native methods of mining are crude and primitive, no machinery being employed, the gravel being raised from the pits in baskets, and the precious stones picked out by hand. It is largely a gambling enterprise. Handling such small quantities of gravel, a man may work for months without finding a stone of any considerable value. On the other hand, he may at any moment find a stone worth a fortune.

Years of costly experimenting were required before the English company succeeded in working out a profitable method of operating the mines. It was found that all the ground of certain value was already taken up by the native miners. The field open for exploitation, then, consisted of trackless jungle and rocky hillside. Not caring to begin with untried ground, of problematic value, the company bought out a large number of the native miners in the valley of the Mogok river. As soon as extensive operations were attempted, such vast floods of water entered the pits that work had to be abandoned. The rainfall there is very heavy, a precipitation of 24 inches having been recorded in three days, so that both the surface and underground flow is very great. In another valley, a few miles distant, a conical peak, known as the 'Hill of the Spiders' (or *Pingu-taung*, in the Burmese dialect), contains many caves, and these were indicated by native tradition as the real home of the ruby. The entire working force available was next put to work in these caves, in the belief that a volcanic pipe, similar to the famous pipes of blue ground at the Kimberley diamond mines, would be found. The first day's washing resulted in the discovery of one of the largest and finest rubies that the English company has ever recovered. That stimulated the engineer in charge to renewed endeavor, appearing to prove conclusively that he was on the right track. Strangely enough, that single large ruby was the only one of value that the Hill of Spiders ever yielded. Thousands of dollars were expended in bootless labor, and months of time were lost, before the conclusion was reached that nothing more than a waste of money was being accomplished.

Pumping Pit at Shwebontha Mine.

All this simply shows that ruby mining, even before the discovery of a method of manufacturing artificial rubies, was not all poetry and profit. It had its difficulties, discouragements, and losses, just like such prosaic enterprises as digging coal or raising potatoes. It is fortunate that the company was provided with ample capital, and backed

by British pertinacity. Otherwise the history of ruby mining in Burma might have ended right there. A mile or so distant from the Hill of Spiders is the Tagoungnandaing valley, small in extent, and impossible of operation by the Burmese on account of the extraordinary flow of water encountered as soon as pits were dug. Pumps were put in to rid the pits of water, and work was begun here with all the native labor that could be hired. At last success crowned the efforts of the ruby miners, and the enterprise was placed upon a paying basis. This little valley was worked out in two years, but the methods employed there have given results equally gratifying in the Mogok valley and other localities in the ruby-producing district. Mining methods seem rather crude, but their best defense is found in the circumstance that they pay. A pit is sunk, 10 ft. square and usually about 25 ft. deep. Then a centrifugal pump is put to work in the pit, gradually draining out the water from the soil surrounding. Then the ground around the pit is dug away, loaded into cars, and hauled to the washing plant. In time the ground is removed down to the bottom of the pumping pit, which is then dug deeper, and additional pumps put in. The Shwebontha mine, which has been operated since April 1894, is now a great open-cut, in successive 'lifts', with a large pool of water in the centre, fed by rivulets coming from all directions. From the pool, the pumps raise 5000 gallons of water every minute. The pumps, mine-cars, and all machinery used are run by electric power, a large dam across the Mogok river, with a fall of 208 ft., generating the power required for these purposes.

It is obvious that the removal of the water is a difficulty that grows more and more serious with every additional foot of depth. To dispose of this once for all, a drainage tunnel 5400 ft. long, 7 ft. wide, and 7 ft. high is being excavated. This will drain the ground to a much greater depth than has yet been attained in the workings, and will carry the water far down the gorge. As fast as the earth is excavated it is loaded into trucks, which are hitched to endless chains and hauled away to large screens, through which it falls, thoroughly shaken and disintegrated, into the washing pans, 14 ft. in diameter. It is now a thick mud, which is worked over and over by rows of steel teeth set in revolving arms. Water running through these pans washes out the clay and light gravel, leaving the heavier materials, including the precious stones. In ten hours 1000 truck-loads of earth from the mine are reduced to 10 truck-loads. In the safety-pans the concentrating process is repeated, as a precautionary measure, but it is found that not more than one per cent of the gems escape from the first washing pans. The materials left in the washing pans are thrown into covered trucks, which are then locked until the sorters are ready for them. Then the mass of gravel, including the rubies, is thrown into a large bin, from which it gradually escapes into a revolving screen, arranged with meshes of different sizes. First the sand is eliminated, then the clean stones and pebbles drop in five different sizes, the last and largest size falling directly upon the sorting tables, and the other four into the 'pulsator'. This is described by the company's manager as a "sort of perpetual-motion jigger which passes the light stuff away into trucks, while the heavy remainder falls into a locked receptacle." From this receptacle it is taken by the sorters. A large sieve is taken by the sorters, filled with the concentrate, placed in a tub of water and worked and shaken until all the heavier materials sink to the bottom. The sieve is then turned upside down, and its contents emptied upon a table, so that the rubies (being the heaviest) are on top. They are then picked out by hand. Every afternoon the sorters take the day's find to the company's office, where the rubies are sorted into fourteen different grades.

In addition to rubies, spinels, sapphires, garnets, corundum, tourmaline, beryl, and fragments of rock crystal are found. For most of this material there is practically no market in Europe, so that it is usually sold to Burmese dealers for any price it will bring. About half a million carats are sold monthly for from $8000 to $10,000. Every two weeks the company holds a sale, when all inferior rubies and other stones that are considered valuable enough to be included in the monthly clean-up sale are auctioned off to Burman, Shan, Chinese, and East Indian dealers. These auction sales are often scenes of great excitement, intense rivalry prevailing among the dealers. Lumps of red corundum are often put up, apparently of little value on account of their poor color; and yet there may be a ruby of perfect color somewhere in the mass. The Burmese are born gamblers, and always anxious to take a chance of that kind. As high as $3000 has been paid at one of these sales for a lump of red corundum that turned out to be worthless.

Mogok, 60 miles from the Irrawaddy river, is a very considerable town supported entirely by the ruby trade. Many hundreds of men are employed by the British company and the native lessees, and buyers flock thither from all parts of Asia. While the British company sends all its finest stones to London, there are no restrictions placed upon the Burmese lessees, who sell their finds wherever they can get the best price. Then the tens of thousands of small and inferior rubies, as well as the spinels, sapphires, garnets, tourmaline, and other gems are distributed all over Siam, China, India, and the East Indies, supplying the major part of the cheap jewelry of the Orient. In nearly every other house in the town may be seen a group of dealers, Burmans, Shans, or natives of India, squatting around a metal plate upon which the stones for sale are displayed. In addition to these private sales, a regular stone bazaar is held every afternoon in some sheds outside of the village. Mogok, in fact, is one of the world's greatest marts for the purchase and sale of precious stones, as the British company does not by any means enjoy a monopoly of fine gems, and prefers that inferior stones be sold in Burma, and thus kept off the European markets. When the drainage adit is completed, it is estimated that it will make available 177 acres of ruby-bearing gravel, estimated to contain rubies to the value of at least $15,000,000, at present prices. In addition to the Mogok valley, which alone will be affected by the tunnel, the Myintada, Enjauk, Yaybu, Loodah, Kathay, Pama, Kyat-pyin, Bernardmyo, and numerous other valleys are known to contain rich ruby-bearing deposits, some of which are being worked by the natives, while others have never been touched excepting by prospectors. Then in addition to the alluvial deposits of the valleys, there are extensive hillside expanses in which rubies are found, but not in sufficient quantities to justify the application of the same methods that are now in use. It is thought that hydraulicking, as practised in California and elsewhere in America for the recovery of gold from similar deposits, will be applicable to these regions. It is evident, then, that the active exploitation of the ruby deposits of Burma has been no more than rightly begun. It is unquestionable, however, that the future of the ruby mines is endangered by the manufactured rubies. These, it is said, can be made at an expense of about 40 cents per carat. They are not imitation rubies, inasmuch as in chemical composition, color, refraction, hardness, durability, and beauty they are identical with the rubies of the mines. Of all the world's gems, the perfect 'pigeon's blood' ruby has long been esteemed the most valuable. Several years ago the largest stone yet found by the British company, weighing only 11 carats when cut, was sold in London for $35,000. A perfect ruby of five carats weight is worth more than ten times the price of a first-water diamond of the same size. In 1875 the financial exigencies of the Burmese government made necessary the sale of two fine rubies. One, when recut by European lapidaris, weighed 38 $^{9}/_{16}$ carats, and sold for $100,000. The other weighed, when recut, 32 $^{5}/_{16}$ carats, and sold for $50,000. These are among the finest rubies that have ever reached the Occident. It is true that there are larger rubies among the crown jewels of France, Russia, Portugal, Spain, and England, and even in several private collections, but most of these are Ceylonese or Siamese gems and lack the perfection of color that makes the Burmese stones the world's standard of excellence.

Rand Metallurgical Improvements

By R. W. Schumacher

*Considerable improvement has been effected during the last year in our metallurgical work. I refer, in the first place, to the Butters vacuum-filter which was put in at the Crown Mines and formally taken over by the company after a most exacting trial of six months' duration. Tests were made first on current slime, then on a mixture of current and accumulated slime, and finally on residue from the existing slime plant after washing treatment by the Adair-Usher system had taken place. The most important points to be determined in these tests were: (1) To what extent could the gold in solution be recovered? (2) What would be the cost of this recovery? The six months' trial showed that the recovery of gold was practically complete, the minute quantity of gold in the final residue being due to traces of unprecipitated gold in the solutions used as washes. As regards the cost of treatment, the operations of the plant at only one-third of its capacity and under conditions requiring an abnormal consumption of acid in clearing the filter-leaves, made it difficult to arrive at finality. But it can safely be deduced from our Crown Mines experience that at a plant working normally on current slime, the cost of operating should be somewhere between 2d. and 4d. per ton, according to the tonnage treated. The final test at the Crown Mines showed a recovery of over one shilling per ton from residue already washed by the Adair-Usher system. The results of the vacuum-filter plant have, so far, been decidedly satisfactory, and show a distinct improvement on former methods of treating slime, so that on the advice of the chief metallurgist of the company, F. L. Bosqui, the same type of plant is now being erected at the Bantjes Consolidated Mines, Ltd., the New Modderfontein G. M. Co., Ltd., the Robinson G. M. Co., Ltd., and the Modderfontein B. Gold Mines, Ltd.

The Merrill zinc-dust precipitation process has also been ordered for the New Modderfontein and the Modderfontein B. The advantages consist chiefly in the lower consumption of zinc, and the saving in labor. This process has also, together with the Butters filter, the advantage of introducing greater precision into metallurgical calculations. The zinc-dust system admits of a more accurate determination of the gold precipitated from day to day, and gives a complete clean-up, so that there is little chance for error in estimating the gold carried over in the zinc from month to month, as in the existing system.

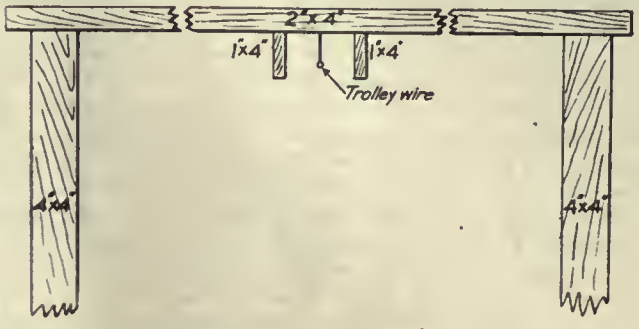
Barytes as a Pigment

One of the principal uses of barytes is as a pigment in mixed paints. It is used in the finely ground, bleached, and floated condition and is a constituent of lithopone. Barytes and blanc fixe (artificial barium sulphate) belong to the class of pigments called inert extenders and reinforcing pigments, along with such other minerals as gypsum, whiting, asbestine, and silica. In the past the overloading of mixed paints with inert pigments has been the main cause of a strong prejudice that has grown in the minds of consumers against the use of such pigments. So-called 'pure-paint laws' have been enacted in certain States, making it compulsory for paint manufacturers to label all paint packages with the formula of the contents. In connection with this movement toward paint legislation the thorough testing of mixed paints has been carried on during the last four years by a committee representing the Masters Painters' Association of Philadelphia and the scientific section of the Paint Manufacturers' Association of the United States, which reports that these materials have no especial value as pigments when used alone, but that their intelligent use within certain limits is necessary for the production of a satisfactory mixed paint.

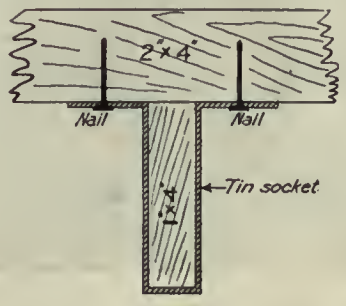
*Abstract from report of the annual meeting of the Rand Mines, Ltd., published in *The South African Mining Journal*, March 25.

Trolley Protection

The increasing use of overhead trolley wires in and around mines makes important any devices for minimizing the danger of men coming into contact with them. While the current used varies, it is always of sufficiently high potential to severely shock and often to kill. Different individuals exhibit unlike degrees of susceptibility to electric shock and the same person under different conditions may be killed, burned, or shocked by current of the same voltage. In mines the wires are usually strung at one side, or high enough to be out of the way of a man walking under them. It is impossible, however, by these means



alone to prevent accidents due to contact through tools or pipe carried on a man's shoulder, and it is equally impossible to prevent men from resorting to this customary manner of carrying a load. At the Harvard mine, near Jamestown, California, where C. E. Shafer is manager,



there is an electric trolley system for carrying ore from mine to mill. The trolley here has been housed-in on each side so as to effectually prevent accidental contact. The details of the method of construction are illustrated in the accompanying figures. Essentially, 1 by 4-in. boards are fastened by means of tin strips to the overhead stringers, in such position as to parallel the horizontal wire. As the wire is hung less than 4 in. from the stringers the effect is to give complete security. At this mine a four-wire system is used, but for clearness only one wire is represented in the figures.

The same system is used at the Melones mines, managed by W. G. Devereux. This mine is opened by a 700-ft. adit. The construction illustrated is only found necessary in and around stations. From the loading station to the entrance of the adit, the trolley is high and the distance is so long that men never walk carrying tools. For transporting men a passenger car has been built, and this is completely covered with a light wooden roof, so as to make it impossible for either men or tools to touch the wire.

Peat is used as a fuel in European countries, but has found but little application to this purpose in the United States, as the amount of the production so used last year was but little over a thousand tons. Peat has numerous disadvantages, the chief being its large content of water (and corresponding low fuel value) and its bulky and friable nature, which unfits it for transportation. These may be partly overcome by drying and briquetting, but the cost of so doing is in most cases too high to be commercially profitable. Plants are in operation in Maine, Massachusetts, New Jersey, Michigan, and Iowa.

Roasting at Kalgoorlie

By M. W. von Bernewitz

At the Associated Northern Blocks, Kalgoorlie, Western Australia, the ore from the Main Lode is of a rather soft schistose character and contains tellurides and pyrite, the sulphur averaging 3%. The ore from the West Lode is much harder, containing practically no telluride, but some graphite and 4% S. All the ore is crushed in Krupp ball-mills through a 27-mesh screen, and fed into six Merton ordinary furnaces. These have three hearths 6.5 by 30 ft. each in the clear, and a finishing floor 6.5 ft. in diameter. The furnaces are run at one revolution in 45 seconds, and absorb 2.5 hp. each. It was found that, with the first-mentioned class of ore, 120 tons per day could be roasted; but with the latter, the tonnage fell off to 110 and 100. The furnace feeders, simply small screws in a cast-iron tube at the top floor of the furnace, and driven by sprocket wheels and chain, are arranged for different quantities. The Merton furnaces here are fairly satisfactory, but at times difficult to regulate. On the top hearth the ore is merely warmed. Roasting commences on the second, while on the third hearth most of the sulphur is eliminated, helped, of course, by the action on the finishing floor. The temperature is not easily regulated, and the third floor is depended

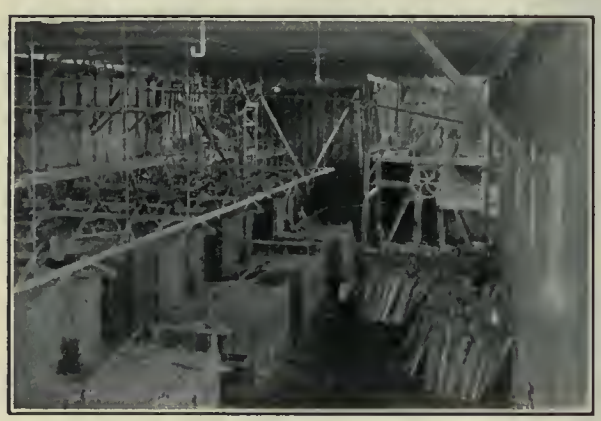


Fig. 1. Interior of Associated Northern Mill, Showing Merton Furnaces.

upon to do too much work. The flue-gas averages 600°F., a mercury pyrometer being fixed in each goose-neck flue that connects with the main and stack, the latter 100 by 6 ft., bell-bottomed. The draft averages 0.5 inch in the main flue, dropping to 0.02 inch at the fire-box. There being so many turns in the furnace, the draft is checked somewhat. If the furnace was fired too heavily, the ore tended to 'ball,' and the roast would test poor. This 'balling' is a peculiar thing in roasting in Kalgoorlie ores, and was discussed at one of the meetings of the Australian Institute of Mining Engineers. When the heated ore 'balls,' it does not get hard, as the slightest touch with a bar will break it up again. One metallurgist thought that it must be the result of a change in the lime in the ore during roasting to $CaSO_4$. Another said that possibly the schistose nature of the ore would account for it. However, it is rather interesting, and if the lumps are discharged from the furnace, they enclose particles of ore not properly roasted; hence, it is desirable to prevent their formation.

On firing up afresh, it is found advantageous to let in an extra quantity of air for perhaps one-quarter hour, until the firewood is well alight, there being a deficiency of oxygen at this time, due to the new fuel. It is not customary to fire continuously, as tests showed that, if this were done, the soluble sulphides in the roasted ore were much higher than when firing was intermittent. Roasting the heavy sulphur ore after it had been crushed through a 30-mesh screen was tried, but the result was little better than with the coarser material.

In connection with the subject of furnace design, namely, superimposed hearth furnace and the straight-line type, the remarks of J. E. Edwards in 1909 before the Western Association of Technical Chemists and Metallurgists should be read. At the Associated Northern, the formation of sulphuric acid has been noticed for years, on the arches under the furnaces where the footstep bearings of the rabble spindles are. This acid is highly concentrated, and is less noticeable toward the finishing hearth. Its formation was puzzling for a long time, but it is probably due to gas drawn down between the spindles and bottom hearth, and condensing on the cool arch outside. Fuel consumption averages 14% of weight of ore fed into the furnaces. The discharged ore is taken by a short push-conveyor to an elevator, and from this into a mixer, and mixed with 0.04% KCN solution. The resulting pulp flowing to the pans is very hot. There does not appear to be any extra consumption of cyanide on this account, and fully one-half of the gold in the ore is in solution at this point, so much so that, when roasting is good, no more cyanide is added to the agitators, which only work for four hours. For a quick, though rough, test of the roasted ore, the lead acetate method is used; while for accurate work in determining soluble sulphides the iodine test is used. The cost of roasting averages 66c. per ton roasted.

No accurate estimate of the amount of the dust saved

Fig. 2. Stack of Roasting Plant, Giving Off Arsenious Oxide Fume.

was ever made, and as for determining stack losses, that is rather difficult. The dust is raked out at regular intervals into a small push-conveyor, and is elevated to the fine-ore bin, mixing with the raw ore from the mills to be roasted. This mixture roasts fairly well, but the half-roasted flue-dust tends to make the ore flow very fast in the furnaces. The dust from the ball-mills was drawn off by a fan, and blown into a canvas-lined house for collection. This stuff was exceedingly fine, less than 200 mesh, and roasted well. In the furnace it puffed up a good deal, and gave the impression of a tremendous feed coming through. The ball-mill dust is now blown into the furnaces on the second hearth. Part of the Northern mill is set apart for custom work now, and some interesting lots of ore come in for roasting. Perhaps the most interesting lot was one of 40 tons of concentrate containing over 20% arsenic. One Merton furnace dealt with nine tons daily of this, giving a splendid roast. As soon as the concentrate was fed into the top hearth it caught fire, and the sulphur and arsenic were well out before the end of the third hearth. Dense white fume of arsenious oxide was emitted from the stack, and quickly settled to the ground, but there were no complaints.

The ore at the Associated mine is hard and high in sulphur, the average during the month these notes were written being 5.5%. The ore that comes from Tetley's section of the mine runs as high as 7% S. The ore is crushed in Krupp mills through an average screen of 28 mesh, and the fine ore is fed into 17 ordinary Merton, one Associated, and two Edwards duplex furnaces. The Merton furnaces

were built badly at the start, and reconstruction has not helped them much. Being generally in poor order, their capacity on this ore is only from 10 to 15 tons each daily. Four of them were experimented with on the following lines. On one the finishing hearth was extended about 7 ft., this making three rabbles working in the hottest part of the furnaces; on another furnace the finishing floor was extended to admit putting in an extra rabble; the third was rebuilt similar to the first, only that it had a stack of its own to test the draft; while on the fourth a fire-box was built at the back of the second hearth. The ore roasted gets too hot near the feed end, while the work of the other three is a slight improvement over that of the ordinary type.

The Associated furnace, devised by Messrs. Daggar and Bull, is rather interesting. It has two hearths, each 46 by 6 ft., and the feed travels along the top floor to the fire, drops through a port on to the second hearth, and is rabbled from the fire to the discharge end. The fire has no connection with the bottom floor at all. This is not simply a cooling hearth, as when the ore drops on it, not more than 50% of the sulphur has been eliminated. Here it burns away until the third rabble from the discharge, when the ore cools off quickly. The furnace has 14 rabbles on each hearth, traveling at 3 r.p.m., the rabble in the fire end going at 6 r.p.m. It has a stack of its own, with 0.55-in. draft. The stack for this furnace is erected close to the discharge end, there being only a flue of a few feet. With such a strong draft, a fair amount of dust results. A screen test

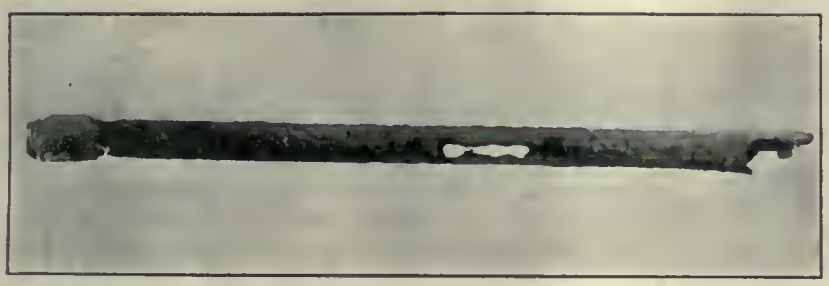

Fig. 3. Water-Pipe in Rabble; Showing Corrosion.

of the dust left in the flue, quoted below, shows that practically only coarse particles are left behind.

The daily capacity is 27 tons, and the roast is rarely poor. Fuel consumption is about 11%. I think that, some years ago, J. A. Greenawalt, of Cripple Creek, also advocated this principle in roasting.

The Edwards duplex furnaces do admirable work on the heavy sulphide ore. The two in use are not exactly similar. The hearth area, common to both, is 11.75 by 107 ft., with three fire-boxes, each 6 by 2 ft., No. 1 furnace has the first fire-box 56 ft. and the second 66 ft. from the feed end, the third being at the discharge end. This furnace has a fall of 0.25 in. per foot, and the rabbles travel at 4 r.p.m. In No. 2 furnace the fire-boxes are 42 and 66 ft. from the feed end. It has a fall of 0.31 in. per foot, while the rabbles travel at 2.62 r.p.m. The draft averages 0.55 in. There are 52 rabbles in each furnace, 32 of these being water rabbles. Hot water circulating in roasting plants is, for some reason not yet understood, very corrosive. It eats away pipes wholesale, especially the water-pipes in the rabbles. A ¾-in. iron pipe may last a year, when it is riddled with holes, as will be seen in Fig. 3. Copper pipes have been used on some mines with some success. The rabbles used here are cast at the mine, and instead of having a pipe to the toe of the rabble, a web is cast in the rabble about ½ in. thick, and this gets over the trouble.

In the No. 1 Edwards, the ore gets a dull red about the fifth rabble from the feeder, while in No. 2 it starts quite near the end, and this furnace does the better work of the two, with about 10 tons more capacity daily, simply because of the first fire-box being nearer the feeder, the extra fall, and slower rabbling. The furnace feed conveyor is fed by a screw, from the fine-ore bin, driven by cone pulleys giving about 75, 90, and 105 tons of ore to each furnace daily. Recently they have averaged about 95 tons each. They are motor-driven, and use 6 amp. at 550 volts each, the ammeter being a splendid guide as to the amount of ore fed into the furnace. These furnaces are easily regulated, and if results are poor at any time, they are stopped for a few minutes, then run slow for perhaps a quarter of an hour, and fired heavily, letting in plenty of extra air. In about half an hour a bad roast is entirely corrected. The end fire-boxes are not used much, just two or three logs are kept burning to warm the air passing through the fire-bars. I might say here, with reference to bad roasting, that often this end fire-door is left open to let in an excess of air. It would seem that certain liberties may be taken with such high sulphur ore, much different to an ore carrying only 3% S. The middle fire-boxes are fired heavily, and the sulphur continues to burn till the fourth rabble from the discharge, namely, 22 from the feed end, and then discharges quite cool. Fuel consumption averages 11% of the ore roasted. The flue temperature is 700°F. One man attends two furnaces, and they are greased only on day shift. On these furnaces roasting costs about 60c. per ton, while the total cost for the whole roasting plant is 80c. The roasted ore is elevated and mixed with 0.03% KCN solution, and unless roasting is poor, the consumption is low, and a great deal of gold is dissolved here, the final pulp being agitated for 1½ hours with 0.065% solution in A. Z. agitators.

Since the above notes were compiled, the Associated mill is being overhauled and remodeled, with a view to cheaper and more efficient work. In the roasting department, eight Merton furnaces have been dismantled, and the nine remaining shut down for good, and the flues torn out. In place of these, two Edwards duplex are being erected similar to No. 2 described, while the fire-boxes of No. 1 will be altered also. It is hoped with the four furnaces to deal with 10,000 to 12,000 tons monthly. Except the brick, every part of the roasters is being made in the mine's foundry and fitting shop, so they will be erected at a minimum cost. This, with the lowered cost of roasting, should allow a marked decrease in treatment cost.

Oil-Land Withdrawn

The petroleum lands in the public-land States constitute one of the most important natural resources remaining in the hands of the Federal Government. As a result of investigations by the United States Geological Survey large areas of these lands have been withdrawn from public entry pending legislation needed to prevent their wasteful exploitation. On April 1, 1911, these withdrawn oil lands aggregated near 4,000,000 acres. The States in which they are situated and the acreages are shown in the table which is given below.

	Acres.
Arizona	230,400
California	1,594,332
Colorado	87,474
Louisiana	414,720
New Mexico	419,901
Oregon	74,849
Wyoming	392,306
Total	3,795,548

Improvements in Assaying

By Abbot A. Hanks

*It is interesting to note the changes that have taken place in the last twenty-five years in the apparatus and methods used in fire assaying. In the early eighties, assay furnaces were ponderous affairs built of fire-brick and fired with coke or charcoal. Here on the Pacific coast we could not use local coke and our fuel was the so-called 'English' coke imported from abroad, principally Belgium, at a cost of from $20 to $25 per ton. The furnace was mounted on a base in order to bring the muffle to the proper height. On account of the smoke and heat special chimneys were necessary. In the city, where furnaces were connected with flues in ordinary buildings, there was continual danger of fire from over-heating. All crucible fusions were made in a special crucible or wind-furnace. Where the assayer was not burdened with an abundance of work, he generally made one furnace do for both fusions and cupellations. The muffles were small, usually not over 6 in. wide, and held from 6 to 12 cupels. Modern muffles hold from 20 to 30. Space around and under the muffle was filled with burning fuel. The charge-door above the muffle permitted the introduction of crucibles which were imbedded in the hot coke. If the fire was not properly built up it burned away completely in the 40 to 50 minutes required for fusion and the crucibles fell over and spilled the charge. There was always danger of the coke getting into the crucibles, and they are frequently covered with fire-clay lids. These covers induced boiling, and where the pots did not boil over the charge frequently stuck to the bottom of the cover. It was not customary to use nitre in those days for oxidizing the sulphide ores. In some cases the heavy sulphides were given a preliminary roast in a flat roasting-dish in the muffle.

The other method was the use of just enough litharge to give the proper size lead button, while the excess of sulphide was taken care of by adding iron nails. This gave dirty slags, and in a heavy sulphide ore the nails would eat through or form matte, which adhered to the lead buttons. The wind-furnace held 4 to 8 crucibles to a charge, while the combination fusion and muffle furnace usually held 2 to 4. Now in the large muffle furnaces 15 to 25 can be run at once, according to the size of the muffle, and of the crucibles used. When cupellation was carried on in a furnace used also for fusions, the temperature of the muffle would vary with the condition of the furnace, being high when the fusions were about ready to pour, and low when the new lot of crucibles had been charged. Of course, with this wide variation of temperature, careful cupelling as it is understood today was impossible. Although silver at that time was selling for its full coin value ($1.29 per oz.), closer check than 1 oz. was not expected even on low-grade ores. The gold and silver button was parted in a test tube, using comparatively strong nitric acid and heating the test tube over the flame of a bunsen burner or alcohol lamp. Under this energetic action the gold broke up into a fine powder. In fact this breaking up was considered necessary to insure proper parting. When the silver had all dissolved, the acid solution was decanted and the test tube filled with distilled water. It was inverted over a small clay annealing cup and when, in the opinion of the assayer, the gold had all settled into the cup, the tube was slipped off with a dexterous motion of the hand, the cup dried and annealed.

Few balances were made in this country, all the fine scales coming from England and Holland. The beam was not graduated to its full length and frequently there was difficulty in getting an exact weight where the button registered less than 1 mg. and more than $^{9}/_{10}$ mg., this latter being the highest weight which could be read on the beam with the rider.

*Read before the California section of the Amer. Chem. Society.

Samples were prepared by breaking down large lumps with a hammer on an anvil, or were given a preliminary crushing with mortar and pestle. The mortar has made more trouble in salting samples than any other piece of apparatus. Energetic action with the pestle wears pits in the bottom of the mortar, and particles of free gold are driven into the little holes, where they remain to be gradually ground out as successive samples are pulverized, much to the detriment of accurate work. The final pulverizing was usually done on the bucking-board. As this was pretty hard work, the assayer or his assistant contented himself with putting through just enough pulp for one assay. Instead of grinding from 8 to 12 oz. through 80 to 100-mesh screen, a 2 or 3-oz. sample ground to pass 40 mesh, or in special cases, 60-mesh, was considered good enough. A strong man could buck down a 6-lb. sample in from 12 to 15 min., while now by machinery a sample twice this size is ground to a much finer mesh in 5 min. It must be remembered that in those days there was in our cities no easily available source of power. Electricity was not then supplied to the business portion of the city as it is today, and the assayer who required power would have had to put in a steam plant or gas engine.

The first crusher which I remember was the John Taylor rock fine-crusher. It was a hand machine on the lever principle, which enabled us to crush samples of several pounds each to a uniform product of ¼ in. or finer. It could be readily cleaned, and it was a great improvement over the old method of breaking large samples with a hammer. This was followed by power machines, both crusher and grinder; most of these, however, were large machines, requiring considerable power, and more adapted for the use of smelting and sampling works where big samples had to be prepared. The first crusher which I used was the Bosworth, manufactured in Denver, a ponderous little machine which, however, was not strong enough to be driven by power and gave a good deal of trouble. One of the early pulverizers was the Luckhardt grinder built on the same principle as the Braun pulverizer, but of course much more crudely constructed. With the introduction of electric power, laboratory crushing and grinding machinery has been improved until today it is possible to obtain rock breakers of steel, built just as carefully as the machines of full size used in large mills, and capable of crushing from 150 to 500 lb. per hour to ¼-in. size, with every facility for careful cleaning between samples. Our pulverizers can be set to grind to 100 mesh and even finer and can also be perfectly cleaned after grinding each sample.

The first radical improvement in assay furnaces dates back to the invention of the gasoline burner. In England, where illuminating gas was cheap, the gas muffle-furnace has been used for many years in the mint and Government assay offices. In this country, however, the high price of city gas has until within the last few years prevented its general use. The first gas burner was the Hoskins, manufactured by Mariner & Hoskins, the well known assay firm of Chicago. While this burner had many disadvantages, it foreshadowed better things. The gasoline flame is intense and can be confined to a small box. There is no smoke and small furnaces are used which can be placed on an ordinary work-table. Frequently no connection is made with the flue, the small amount of gas and fume generated passing into the room. It will be seen at once what a radical change this involves from the unwieldy coke furnace which had to be frequently rebuilt or relined. There was an enormous saving of labor in handling fuel and ashes, and as there was practically no dirt the furnace could be placed in a room where the more delicate operations of assaying were carried on. The Hoskins burner, however, never found favor on the Pacific coast. It could not be used for cupelling, owing to the fact that a reverse draft was created in the muffle which prevented the cold air from entering and stopped oxidation.

Frank Fielding, head assayer of the Con. Virginia mines, of Virginia City, invented and patented, about 1885, a gasoline burner that was a great improvement over the Hoskins.

At that time Mr. Fielding was in charge of a plant which ran assays for all the Comstock mines. With several assistants he turned out from 150 to 200 assays per day. Mr. Fielding constructed a large number of small crucible furnaces, each capable of holding four pots and each equipped with its own burner. The furnaces themselves were not much larger than 1 ft. cube, and were placed on a worktable covered with sheet iron. With this plant Mr. Fielding and his assistants were able to fuse from 50 to 75 assays per hour; an unheard of amount of work in those days. But he was forced to use coal or coke furnaces for cupelling.

The first notable advance in gasoline-burner construction was the advent of the Cary burner, put out by Braun of Los Angeles about fifteen years ago. In this burner the proper principles were applied. A needle-valve permitted the perfect regulation of gasoline vapor and the combustion chamber did away with all trouble of flashing back. Improvements have been steady in burners, tanks, and pumps, so that now the apparatus of the assayer is portable, even to the gold balance, and can be carried on muleback to almost inaccessible localities. There have been improvements also in gas burners and many large offices are using city gas for both fusion and cupellation work.

The introduction of oil has been of great importance on this coast and this fuel has been adapted to use in the assay-furnace. A number of large mills and reduction plants using crude oil for fuel have introduced this also for their assay-furnaces. It gives a satisfactory heat, but it requires a large fire-box, and if the furnace is not properly constructed the hottest part of the flame will be in the chimney instead of around the muffle. Stove distillate of 28 to 32° gravity is better than crude oil for furnace work and almost as cheap. It flows more freely, giving no trouble even in the coldest weather. It is not explosive and does not carry the water and grit found in crude oil. It burns with a shorter flame and apparently gives just as much heat. In the old days all silver assays were run in scorifiers in the muffle. In Colorado, where at that time most of the ores assayed were silver ores, this led to the building of large coal furnaces carrying two or three muffles each. The scorification assay has its limitations, however. Only a small amount of ore can be used, and the results on gold are generally low. It was not long before small crucibles were run in the muffle and now the best practice calls for running all fusions in the muffle rather than in the open or pot-furnace. This method has many advantages. The heat of the muffle is more even and all crucibles receive the same treatment, while in the direct-flame furnace the crucibles nearest the burner are hotter than those farther away. The muffle holds 15 to 20 crucibles, which are all charged at once. They require very little attention for 30 to 50 min., during which time the assayer can busy himself about other work. In the direct-flame furnace it is necessary to pour and recharge a set of pots about every 10 min. The muffle is not nearly as hot as the open furnace and so is much easier on the operator. After all fusions are complete the temperature is lowered and the lead buttons are cupelled in the same muffle.

In few of the modern assay offices are silver buttons parted in test tubes. Almost all assayers now treat twice with nitric acid of different strengths. A weak acid of about 1.11 sp. gr. (18% HNO_3) is first run on which dissolves the bulk of the silver. The button is given a final treatment with stronger acid of about 1.32 sp. gr. (50% HNO_3) and then washed. In the old method of treatment in the test tube with one boiling with strong acid there were undoubtedly considerable losses in fine gold which was broken up to a powder by means of the violent action and which did not settle but floated off in decanting. The present custom is to flatten the silver button and place it in a porcelain cup. Here it is treated with the two strengths of nitric acid, washed, annealed, and the fine gold brushed from the parting cup directly to the pan of the balance. It is possible to part buttons containing a large excess of silver and still retain the gold in one lump or mass, and as there is no transfer, the possibility of loss of gold is reduced to a minimum. Some assayers still part in glass, using small Erlenmeyer flasks.

There have been great improvements in balances for assay work. The long-armed machine of twenty-five years ago was quite accurate, but altogether too slow for the requirements of the modern assay office. We are frequently required to weigh up 50 to 75 gold buttons at the end of the day's work. To do this with the slow-moving long-armed Ortling balance in use twenty-five years ago would have been almost an endless task. Now a good operator can accomplish this in 1 to 1¼ hours, or at the rate of about one button per minute. The Keller type of balance is finding favor now for the most delicate work. This balance is made with short hangers, the distance from the knife-edge to the pan-support being about two inches as compared with nine inches in the older type. This makes a low and self-contained instrument, not easily affected by any ordinary amount of jar, and holding its adjustment well. The needle is inverted, indicating on an ivory scale above the beam. The beam is not itself graduated, but the position of the rider is indicated on a scale behind the beam by a pointer on the carrier. The best balances of this type will readily indicate 0.005 mg. and can be kept at this sensitiveness under the demands of daily work. Another improvement is the multiple rider attachment. A number of riders of different weights are held on suitable racks above the beam. A special carrier enables any one of these to be placed on a hook on the stirrup. In this way buttons up to 30 mg. can be accurately weighed by a combination of riders without placing any weights in the pan or opening the door of the balance.

The assayer is now able to secure very accurate riders and assay weights. Sets of weights can be secured which have been compared with the standard gram in the U. S. Bureau of Standards, Washington, D. C., and graduated to be accurate to 0.005 mg. These weights do not retain their accuracy even in the hands of a careful operator, but become heavy. The lip of the weight gets rough under constant handling with the pliers, and dirt and dust are rubbed in, making the weight heavy. All assay weights of 5 mg. and less used for delicate work should be checked against a standard weight every six months.

The art of assaying is as old as metallurgy itself. Agricola, whose work on metallurgy was published in the early part of the seventeenth century, shows a cupelling furnace that was operated in a manner similar to that now in use. It is questionable whether assaying was then applied to ores. Probably it was used as a means of refining gold and silver alloys. In the United States it is only within comparatively recent years that the position of assayer has been considered of any importance. At most of the mines when it was thought advisable to have an assayer, he was about as useful as the paper-weight on the superintendent's desk. The position was filled by some young man not capable of doing hard physical work, usually a relative of the president or of some large stockholder. There are in the assay business a great many rule of thumb men who have been instructed by such men, and who have no knowledge of the principles of chemistry or metallurgy. There are the usual number of quacks who do not know anything and who do not attempt to assay the samples entrusted to them. Assayers have also fallen into bad repute through 'high-grading.' At all mining camps where rich ores are produced the miners and those employed underground manage to steal a great deal of rich ore. This ore is brought to the surface concealed in their clothing, in their ears and mouth, or other parts of the body. It is necessary to find a market for this ore, which is known by the name of 'high-grade.' In all such camps there are so-called assay offices that are merely 'fences' for the disposition of stolen ore. Such places are only called assay offices as a blind. In Goldfield there were, at one time, twenty-three of these assayers. A miner would take his stolen ore to the office of Smith, where it was crushed, and a sample given to him to be run by an independent assayer, as a check. This sample he would

perhaps take to the office of Jones. Jones, noticing the name of Smith on the pulp envelope, would telephone Smith to know how much he was going to allow for the ore. When Smith replied, Jones wrote out an assay certificate for the amount, while the assay sample was thrown aside without being opened. There is no more reason to call a man presiding over this sort of an establishment an assayer, than there is to dignify the name of the manager of quack medical institutions with the name of Doctor.

The estimated value of ores bought and sold in the United States alone on the basis of assay is over $1,500,000 per month. This does not take into account the enormous amount of bullion handled through the mints and U. S. assay offices, but applies only to ores purchased by smelters, sampling plants, and custom mills. At every such plant and at every gold and silver mill of any size throughout the country the operations are controlled by assays. The accuracy of assay methods is far in excess of that required in ordinary chemical determinations. Gold determinations must be accurate to 0.01 mg., equivalent to 1 part in 2,900,000 or 0.00003%. In addition to the products bought and sold on the results of fire assays, consider the enormous amounts involved in the sale of mining properties that change hands on the results of samples, which are all assayed by fire method.

There are a great many mistakes made in mining, and a great deal of dishonest work is done. Speculation in mining shares is rife all over the world, and the unthinking public calls this mining and blames the certain losses which result, to one of the largest and most necessary of our natural industries. Mining shares are simply used as a means of indulging the desire of the average man to gamble, and there is no more relation between playing the stock market and legitimate mining than there is between the betting ring and the scientific breeder of blooded horses. It frequently happens that mistakes and errors are magnified while a large amount of good work passes unnoticed. Many of the errors charged against the assayer are not his fault and are due to improper sampling. The assayer can only work on the sample brought to him, and it is astonishing to find how many mining men are wholly ignorant of this important detail. A man will bring a single piece of ore of about 2 lb. weight and say, in all seriousness, that it represents the average of a mine which has perhaps 200 ft. of development. Or he will bring in three or four lumps of ore the size of apples, which he claims to be an average of a dump of several hundred tons, while in the same breath he may say that he picked out the worst-looking pieces, rejecting those that showed free gold because he did not wish to obtain too high results. With such ignorance on the part of the mining public, is it any wonder that there are discrepancies in assays or that the metal found in crudely selected grab-samples fails to materialize when the ores are milled or sent to the smelter?

Improvement in apparatus and methods is rapidly extending the sphere of the assayer, and his work is becoming better known. Where not long ago the superintendent expected his assayer to check with what he thought the mill was doing, we are now beginning to feel that the results of the assayer are the real index of what the plant is accomplishing. To do this we must first have well-trained conscientious men, supplied with the proper and accurate apparatus, given a decent place to work in, and not overworked. With these necessary conditions filled, we have reason to expect and to insist on accurate work.

LEAD AND ZINC in large quantities are secured by working over the drosses, old metals, and alloys resulting from commercial operations. Lead so obtained is chiefly derived from skimmings, drosses, old metal, and alloys; solder, type-metal, and babbitt, for example. The amount obtained in this way was over 40,000 tons in 1909. Secondary zinc is chiefly obtained from the drosses and hard zinc produced during the operation of galvanizing, but an appreciable quantity is obtained from various zinc alloys, the total for 1909 amounting to about 35,000 tons.

Goldfield Consolidated

The following is a summary of operations and costs for the first five months of the current fiscal year, November 1910 to March 1911, inclusive, of the Goldfield Consolidated Mines Co. and Goldfield Consolidated Milling & Transportation Company:

	Total.	Average.
Ore milled, 126,872 tons, value	$4,361,234.22	$34.38
Loss in tailing	270,115.56	2.13
Net recovery	$4,091,118.66	$32.25
Ore shipped, value	156,440.58	727.63
Values realized	$4,247,559.24	$33.42
Mining:		
Mohawk shaft	136,373.84	3.35
Combination shaft	52,405.60	2.17
Red Top shaft	96,843.28	5.10
Jumbo	163,232.28	3.78
Total	$448,855.00	$3.53
Transportation	13,757.91	0.11
Milling:		
100-stamp mill	269,166.72	2.12
Concentrate treatment	49,450.09	0.39
Total	$318,616.81	$2.51
Marketing:		
Bullion	22,334.55	0.18
By-products	3,941.67	0.03
Concentrate residue	58,539.54	0.46
Total	$84,815.76	$0.67
General expenses:		
Administration	15,734.01	0.13
Manager's office	5,183.38	0.04
Secretary and treasurer's office	5,176.34	0.04
Legal expense	12,411.12	0.10
Insurance	397.95	0.003
Mine Operators' Association	2,815.07	0.02
Damages	3,155.25	0.03
Property tax	2,657.14	0.02
Corporation expense	14,139.76	0.11
Sundries	18,040.48	0.14
Total	$79,710.50	$0.63
Bullion tax	54,449.34	0.43
Marketing high-grade ore	13,562.74	0.11
Construction	97,466.74	0.77
Total costs	$1,111,234.80	8.74
Miscellaneous earnings	17,815.29	0.14
Net costs	$1,093,419.51	$8.60
Net profits	3,154,139.73	$24.82

MICA is used in large quantities in both sheet and ground form. Sheet mica is used in stoves, gas-lamp chimneys, lamp shades, for glazing purposes, and in many kinds of electrical apparatus and machinery. The electrical industry consumes by far the greater part of the sheet mica produced. Mica serves as a perfect insulator in various parts of dynamos, motors, induction apparatus using high voltage, switchboards, and lamp sockets. The domestic mica is satisfactory for all insulation except for commutators of direct-current motors and for dynamos built up of bars of copper and strips of mica. For this purpose no mica is as satisfactory as the phlogopite or 'amber' mica. This mica is of about the same hardness as the copper of the commutator segments, and therefore wears down evenly without causing the motor to spark. A large quantity of the small sheet mica used in electrical apparatus is built up into micanite or mica board, the thin sheets being built up layer after layer with shellac, with or without tissue paper, and then subjected to great pressure.

Copper Producers' Association Report

The monthly report of the Copper Producers' Association for April shows an increase in stocks on hand of approximately 3,548,000 lb., compared with a gain of 5,370,000 in the preceding month. Production for April amounted to 118,085,223 lb., a decrease of about 12,500,000 from March. Domestic delivery was only 52,407,650 lb., a falling off of almost 14,000,000 from the preceding month, and foreign delivery, which was supposed to have been very heavy for April, amounted to but 62,129,599 lb., or a gain of a little more than 3,000,000 over last March. Total deliveries for April were 114,537,249 lb., or less by 10,624,667 than in March.

Foreign Visible Copper Supply

The foreign visible copper supply in England, France, and afloat thereto on May 1, 1911, was 78,069 tons, a decrease of 1534 tons within the past two weeks. Below is given the foreign visible supply at the beginning of each month since January, 1909 (in tons):

	1911.	1910.	1909.
January 1	83,797	109,022	55,677
February 1	83,196	110,808	52,935
March 1	82,387	113,455	52,295
April 1	82,267	111,432	51,354
May 1	78,069	110,207	50,918
June 1	.....	106,815	56,854
July 1	.....	103,957	67,379
August 1	.....	99,239	76,559
September 1	.....	97,507	88,218
October 1	.....	93,961	93,851
November 1	.....	88,422	99,357
December 1	.....	86,250	105,743

Cobalt Silver Production

The shipments from Cobalt during the week ended April 21 were:

	Pounds.
La Rose	311,930
Nipissing	146,130
Cobalt Lake	122,200
Kerr Lake	120,000

The quarterly statement of the La Rose Mines, Ltd., shows that it has cash in bank, ore in transit and at smelters valued at $782,564 and ore at the mine ready to ship valued at $393,640; while the quarterly statement for the Nipissing shows that on April 1 it had cash in the bank amounting to $731,883, ore in transit and at smelters valued at $316,638, and ore ready for shipment valued at $266,711.

Sons of Gwalia Mine

The Sons of Gwalia gold mine is situated near Mount Leonora in the North Coolgardie district of Western Australia. The company was floated in 1898 by the London & Western Australian Exploration Co., of which Bewick, Moreing & Co. were the moving spirits. The management of the mine is still in the hands of this firm. Though not now yielding such rich ore as in the years 1903 to 1905, the mine is in a distinctly healthy condition and promises well for the future. The main incline shaft is down 2503 ft., and in order to protect the dip additional claims have been acquired. Development continues to reveal large bodies of ore with here and there rich shoots. On December 31 the reserves were 3½ years ahead of the mill. During 1910, 162,082 tons of ore was raised and sent to the 50 stamps. By amalgamation 44,002 oz. was recovered, 6326 oz. was obtained from concentrate, 10,106 oz. from sand, 5596 oz. from slime, and 704 oz. from slag and accumulated slime, making a total production of 66,734 oz., or 35s. per ton milled. The net profit, after payment of taxes and making allowance for depreciation, was £112,360, out of which £97,500 was paid as dividend, being at the rate of 30%. The company has taken a share in the promotion of the Northern Ontario Exploration Co., which has been formed by the Bewick-Moreing group to acquire properties in Porcupine.

Railway Operating Costs and Revenue

The table below shows the relative percentage of revenue and of cost of operation of Eastern, Southern, and Western railways for the month of February 1911.

	Total.....	Eastern Group...	Southern Group...	Western Group...
Revenue per cent of total:	%	%	%	%
Freight revenue	69.3	70.4	72.5	66.7
Passenger revenue	22.5	21.1	20.6	24.7
Other transportation revenue	7.2	7.4	5.8	7.3
Non-transporation revenue	1.1	1.0	1.1	1.2
Cost:				
Maintenance of way and of structures	11.7	11.2	13.0	11.9
Maintenance of equipment	17.4	18.7	16.7	16.0
Traffic expenses	2.4	2.2	2.4	2.6
Transportation expenses	40.3	42.8	33.5	39.9
General expenses	3.0	2.8	2.9	3.2
Total operating expenses (excluding outside operations and taxes)	74.7	77.7	68.4	73.6
Daily averages:				
Revenues per day per mile	$30.39	$47.57	$26.39	$22.26
Expenses per day per mile	22.71	36.97	18.05	16.38
Net revenue per day per mile	7.68	10.60	8.34	5.88

British Columbia Land Titles

The question of title is again cropping up in regard to a large territory in British Columbia, and it is possible that the decision of the British Privy Council in the Ophir case may influence the result. The Cowichan Indians lay claim to the Cowichan valley under a proclamation issued in 1763 by King George III in which he confirmed the rights of the Indians to the lands not included in the limits of the colonial governments then existing, or the Hudson Bay territory. This claim British Columbia has never recognized. The Indians, after in vain urging their case for many years, have retained as counsel J. M. Clark, of Toronto, recognized as one of the ablest Canadian exponents of constitutional law, and who, as it happens, successfully argued the Ophir mining case for the Ontario Government before the Privy Council. The claim of the Indians of British Columbia rests on the very same legal points as were decided in the Ophir mining case, so that if the former ruling is sustained when the case comes before the British law lords and the rights of the Indians are upheld, it will mean that the province of British Columbia has acted illegally in granting lands within the Indian claims. Consequently all the titles to mining property in that part of British Columbia will be invalidated. As the case now stands the Imperial Government, to which the petition of the Indians for relief was addressed, referred the matter to the Canadian Government. The latter endeavored to induce the British Columbia authorities to agree to refer the case to the Supreme Court of Canada, but they refused to do so, and the Canadian Government has referred the case back to the British Government.

New York Copper Gossip

The copper situation looks a little more hopeful. The break below 13c. last month brought buyers into the market in greater strength than for some time. The European visible supply shows a healthy decrease in the last fortnight of 3,438,400 lb., and an improved statement was shown by the Copper Producers' Association figures for April. In reality, however, nothing in this regard goes to the root of the matter. Improved methods of extraction and improved ore-handling machinery have brought about a production which outstrips consumption and entails economic waste. Curtailment should be in the development of new properties, not in cutting down production at mines now in operation.

The annual report of the Utah Copper Company was made public last week. It shows a production in 1910 of 85,644,511 lb. of copper at an average cost of 8.069c. per pound, for which an average price was received of 12.672c. per pound. The net operating income from the Utah Copper plant was $3,890,912. Dividends received from Nevada Consolidated were $1,459,775. Other items of revenue were $51,088. Interest charges to be deducted were $187, making a net income of $5,401,588. Dividends totaling $3 per share were paid, a total dividend of $4,648,075, leaving a margin of a trifle more than three-quarters of a million to be carried to surplus account. The Utah Copper is a magnificently conducted enterprise, but in hardly any other business, and certainly in no other kind of mining enterprise, would the payment of so nearly the whole of the net income in dividends be considered justifiable, especially in the face of the unfavorable conditions now ruling.

The Chadbourne fight against the Calumet & Hecla merger has taken the form of an action brought by F. W. Denton, who is general manager of the Copper Range, and who is also a son-in-law of the late Thomas L. Chadbourne. The suit brought in Mr. Denton's name is really in behalf of all the Chadbourne heirs and the other Ahmeek shareholders, who are protesting against the absorption of that company. A temporary injunction has been issued, and in the meantime Thomas L. Chadbourne, Jr., is insisting that an independent examination of the Calumet & Hecla be permitted. The whole question is an exceedingly important one to the Boston market. If the merger is completed, Boston, which has always possessed a wider market for copper shares than New York, will in all probability lose its leadership in this regard. The Lake coppers have been active trading issues, and their absorption will mean that there will be few issues left to invite any speculation.

William E. Corey, former president of the United States Steel Corporation, was prominently mentioned last fall as the probable head of the projected copper merger. This was some months previous to any general talk of Mr. Corey's resignation. It appears to be quite possible that, merger or no merger, Mr. Corey is to give his attention to copper. Mr. Corey and Thomas F. Cole were, for many years, associated in the steel business when Mr. Cole was at the head of the ore department of the Steel Trust. Now Mr. Corey has taken a directorship in the Calumet & Arizona and is expected to become an important factor in the management of the Cole-Ryan properties.

The selling of the Miami Copper Co.'s metal output is to be handled by S. S. Rosenstamm, of the General Development Co., if present plans mature. Mr. Rosenstamm has not been actively in the copper metal market for the past three or four years, but prior to that time he was a very active factor and enjoys as large an acquaintance as any copper salesman in the country. It is said that Giroux will begin shipments in July and that Greene-Cananea will probably go on a dividend basis by the end of the current year. Both events, if carried out as promised, will greatly strengthen the Cole-Ryan group. Mason Valley has applied for trading privileges on the floor of the New York Stock Exchange. If the present movement continues it will not be a long while before the mining section of the 'big board' will include practically all of the important porphyries.

Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

A TUBE which is too small for the use for which it is needed may be expanded by the use of an ordinary boiler expander, or it may be reamed out, if the walls are thick enough to allow this to be done.

TO REMOVE old paint from iron and steel, apply the flame of a gasoline torch until the paint blisters and softens; it is then scraped off while hot. Lye or caustic soda can also be employed to remove paint, but is inconvenient to use, and has a bad effect on the hands of the workmen.

BLUESTONE is a name applied to two entirely different substances; copper sulphate, or blue vitriol, and to a variety of sandstone which is quarried in New York and Pennsylvania and used for building, as flagstones, and for making curbing for sidewalks. Over two million dollars worth of this stone is produced annually.

TOOLS, when not in use, should be protected from rust by a thin coating of oil. Any good non-drying oil will do for this purpose, but a mineral oil is better, as it will not become rancid. Kerosene oil should be avoided, as sulphuric acid is used in purifying the oil, and will cause the tool to rust faster than when no oil is used.

PLUGS in classifiers, settling tanks, etc., can be readily inserted without the operator suffering the inconvenience of a wetting, if the tapered end of the plug be cut off at an angle of about 45°. Turning the bevel from the operator will deflect the stream away from him and result in a gradual closing of the opening to be plugged.

GRINDSTONES that have been allowed to stand in water often show soft spots, which wear away, leaving the stone uneven. It is best to drain the water from the tank each time the stone is used. A stone which has become very irregular can be cut down by fixing a hard piece of steel so that it only touches the high places, and running the stone until these are ground away.

LIMESTONE has a great variety of uses; the largest quantity of it is used in the making of crushed stone for macadam, railroad ballast, and concrete, and about $10,000,000 worth is annually used as a blast-furnace flux. It is also burned as lime, used as building stone, paving, and flagstones, used in paper-making and glass-making, and in the manufacture of carbonated waters and all kinds of alkaline salts.

TO CEMENT leather belts, have both ends clean. If they are fatty, lay them on a clean rag and set a hot flat-iron on them so as to melt the fat, which will be absorbed by the cloth. Mix 10 parts of carbon bisulphide with one part of turpentine and dissolve enough gutta percha (soft rubber) in the mixture to make a thin syrup. Coat the surfaces to be joined with this solution and keep them pressed together until the joint has set hard. This cement is said to work equally well with leather and rubber belts.

LAKE COPPER is a term applied to copper which comes from the Lake Superior district, and has a double significance, due to the fact that the copper from this region differs fundamentally in quality and method used in refining from that produced in other parts of the United States, so that the real significance of the term is to designate the highest quality of copper rather than a particular locality. Lake copper, owing to its superior quality, always sells for a small fraction of a cent more than electrolytic copper does.

Discussion

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

Gold Nuggets of California

The Editor:

Sir—In your issue of May 6 there appears an article entitled 'Gold Nuggets in California,' the first item of which I beg to correct: (1) Date should be January 24, 1848. (2) The finder's name was James W. Marshall. (3) There is no record of James W. Marshall ever being married or having children. (4) The first find was a few small nuggets, and none of them are in the possession of the Society of California Pioneers. (5) There is nothing in either Bigler's diary (the companion of Marshall) or in the diary kept by Sutter at Sutter's Fort which states the weight or value.

WM. F. CASHMAN.

San Francisco, May 8.

Hardening and Tempering Drill Steel

The Editor:

Sir—Having read the comments on 'Hardening and Tempering Drill Steel' in your issues of October 22 and November 12, 1910, I have made several experiments along the line suggested, and watched others sharpening and tempering drill steel. Summarizing my observations, I have come to the following conclusions: Drill steel should never be heated above a medium red; more steel is wasted by forging too hot than too cold. Hot steel works best, consequently the overworked tool sharpener will sometimes almost burn the steel in order to get through quickly. All steel, even cheap grades, will do excellent service if not heated above a medium red. Tempering should be carried on with the utmost care. Judgment and sharp eyesight are essential. A color-blind smith cannot temper properly. Horace F. Lunt's remark about a moderately lighted shop is to the point. It is impossible to work steel in excessive or intense light. I find different waters require different heats for tempering. So do different grades of steel. I prefer rain or snow water or soft spring water. Clear water should be used. If steel is brittle, draw it out over night in a heap of burning charcoal; this will toughen any steel. I prefer plunging after heating to the required degree in a clean fire. Scaly bits should never be immersed.

If the above points are kept in mind and directions followed to the letter miners will have no trouble with their tools. Tool-sharpening is a trade almost amounting to a science. A good tool-sharpener is hard to get, and if found should not be overworked.

LORENZ VON SCHOEN.

Gold Hill Mines, California, April 12.

Cobalt District, Ontario

The Editor:

Sir—In reading the article by S. F. Emmons on the Cobalt district of Ontario, in the *Mining and Scientific Press* of March 18, the suggestion of the compressibility and elasticity of the rocks in connection with the fissuring in which the native silver is deposited occurred to me.

There would appear to have been extensive erosion here, resulting in removal from over the present surface of a tremendous weight of material, some from the present formations, and some, possibly, from formerly overlying formations or from possibly comparatively recent sediments. That this former weight would compress the rocks now being worked and maintain them in a tight, close, compact mass seems probable. With the progress of erosion, simultaneous with the process of secondary enrichment, the gradual reduction of the weight would release these rocks, their elasticity would have a tendency to cause changes from the shapes or relative positions maintained when under pressure, and thus produce a gradual fracturing, creeping downward as the masses were relieved of their burden of weight. To illustrate this, a number of cubes of rubber might be placed on a solid base, bounded by some wall on all sides and spaced $^1/_{16}$ in. apart. If over these a cover be placed and weighted sufficiently to deform the cubes, spread them till all the spaces are closed, and the walls touch those of the adjacent cubes, then upon the release of the pressure, the cubes would resume their shape and the spaces be restored. A still better conception may be obtained by assuming square columns with individual weights placed on each and gradually reducing the weight, whereupon the cracks will open at the top, more than toward the bottom. The difference in the elasticity, or other conditions of the formation at various points would account for the greater depth to which the fissuring has penetrated and to which the silver has followed, in one section as compared by another nearby.

Helena, Montana, March 25. L. S. ROPES.

Republic Mining District

The Editor:

Sir—In a diagramatic sketch, forming plate XI of the report by Joseph B. Umpleby, of the U. S. Geological Survey, on the geology and ore deposits of the Republic mining district,* showing the vertical distribution of gold and silver in the Republic mine, the impression is given that gold decreases and silver increases with depth in the mines of Republic camp; an impression that is almost entirely erroneous. The ratio of silver to gold contained in the ores produced from the several leading mines has been carefully determined from the smelter returns of ore shipped to the smelters and the milling results from ore treated in the camp. In the Republic and Lone Pine mines the average ratio has been two or three to one, while in the Quilp mine the ratio has been as high as fifteen of silver to one of gold, but the depth at which the ore has been mined has evidently had no bearing whatever. In the lower workings of the Republic mine silver slightly predominated when ore containing selenium in the form of selenide of silver was found, but the amount of ground opened is comparatively small. In the mines situated northward from the Republic, up Eureka gulch, the relative proportions of gold and silver vary considerably, the value of the silver being generally in excess of the gold. The ratio, however, differs materially in the different mines. For example, in the Lone Pine the weight of silver in a ton of ore is about three times that of gold, while on the upper levels of the Quilp the ratio of silver to gold was about 15 to 1. On the No. 4 level of the Quilp mine, now being opened into the Surprise ground, a large proportion of silver is found in the high-grade ore, while material having a value of $20 or less per ton usually contains only from one to two ounces of silver. Quite recently that condition was demonstrated when the drift in question yielding $20 to $25 ore containing a ratio of about two of silver to one of gold, ran into a body 6½ ft. wide, with a ratio of 31 oz. silver to 7.4 of gold. The No. 4 level of the Quilp mine is fully 600 ft. deeper than the Jim Clark adit level of the Surprise mine, where the ratio of silver is from four to eight to one of gold. In February a deposit of ore was found on the 50-ft. level of the Quilp mine that was exceedingly rich in silver, from which, in fact, the finest specimens of native silver ever seen in the camp were taken. At the same time on the 500-ft. level the highest grade of ore in the mine was being extracted and contained practically no silver. In the general development of the mines of the camp the ratio of silver to gold contained in the ores has been shown to bear no relation whatever to depth from the surface, but on all of the various levels differs materially, gold predominating in one place and silver in another. Usually the richest ores of the district contain a large proportion of silver glance, but are more

*Washington Geological Survey, Bull. 1.

valuable for the gold than the silver. No matter whether the ores are high grade or low grade, gold usually predominates in value, irrespective of depth.

M. H. Joseph.

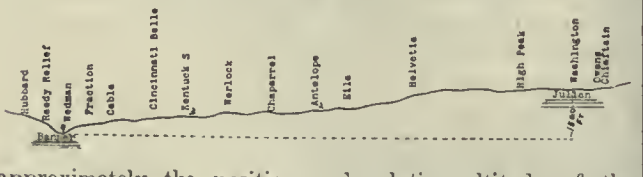
Republic, Washington, March 15.

Surface Indications of Ore-Shoots in Depth

The Editor:

Sir—In his discussion of my original contribution under the above title, in the *Mining and Scientific Press* of October 22, 1910, T. A. Rickard, in the issue of April 8, calls attention to a new phase of the subject, namely, the depth of ore occurrence as related to the present surface. How far Mr. Rickard's theory will apply, I am sure I do not know. I have thought that in a mountainous country, where veins traverse the hills and gulches, outcropping on the highest ridges, down their sides, and often appearing in the bottoms of the gulches or canyons, that it was not unreasonable to expect the veins or fissures observed on the hill-tops to extend downward into the earth at least as deep as the outcrops found in the neighboring canyons. This has been my idea, or hope, though I am not prepared to offer much substantial proof of the correctness of my theory. On the Mother Lode of California the veins are found outcropping on the hill-tops, often forming conspicuous objects in the landscape, as exemplified at Pinion Blanco, in Mariposa county; at Quartz mountain, in Tuolumne county; Carson hill, in Calaveras county; and Seaton hill, in Amador county. In this great lode the fissures extend not only as deep as the levels of the bottoms of the neighboring gulches, but thousands of feet below them. The apex of some of the ore-shoots in these fissures does not come within 1000 ft. of the surface. However, the Mother Lode may be assumed to be an exception to the rule, though the present relief of the country traversed by it is insignificant as compared to the depth already reached by some of the mines along its course. The probable depth of erosion has been estimated at 3000 feet.

I have in mind another region of California, in San Diego county, known as the Julian district, in which a mineralized zone extends across the country in a direction somewhat north of west, for several miles. With a few exceptions, notably the Stonewall and Golden Chariot, the most important mines of the district are situated between the villages of Julian and Banner, four miles distant from each other. Julian is at an altitude of 4200 ft. and Banner is at 2800 ft., a difference of 1400 ft. in altitude. The rocks of the region are mica-slate, mica-schist, and granite. Dikes of pegmatite are common in the mineral zone. There are four distinct lines of mineralization. For the most part the 'veins' occur as a succession of quartz lenses in the schist and slate. So far as I am aware there are no fissure veins in the district. In the Cincinnati Belle mine, near Banner, is found a fissure filled with fragments of country rock and clay, but as far as known it contains no profitable quartz. It lies a few feet distant from and parallel to the auriferous quartz lenses in which is found the real value of the vein. The accompanying sketch shows



approximately the position and relative altitude of the more important mines on the principal lode. There are outcrops of gold-bearing quartz on each of the claims indicated, but none of them have thus far developed into deep mines. These lenses of quartz have resulted from the filtration of silica into a zone of crumpled and folded slate and schist, deformed by a compressive stress which had a tendency to cause a reverse fault (as indicated by local torsion of the rocks), but which stopped short of producing an abrupt fracture. It seems hardly possible that this stress, the unmistakable evidence of which may be seen along the surface and underground for several miles, in these hills, should have been exerted only near the present surface, or even confined to a zone extending from a region 300 or 400 ft. below the present surface up to a pre-existing surface approximately conforming in contour to the present outcrop, a few hundred feet higher. If such be the case, then these veins come within the limitations of vein formation suggested by Mr. Rickard. If the stress extended to a deeper-seated region, then there would be a reasonable probability of the veins of the district also extending to far greater depth than has ever been reached in any of the mines. Several local authorities have variously estimated the output of this district at from $3,000,000 to $5,000,000. The smaller amount is probably nearer the truth. The ore was undoubtedly of good average grade, and some of it wonderfully rich. Without doubt much of the specimen rock so frequently found was the result of secondary enrichment, though ore of this class was found in spots throughout the entire depth of the exploited mineral zone, suggesting that its occurrence was in part due to local conditions, such perhaps, as the crossing seams or other physical features little understood by the miners, and consequently overlooked by them. The veins 'pinched out' in depth, just as they do longitudinally, though in the latter case by drifting in the general direction of the strike, and possibly by cross-cutting, the lenses of quartz were rediscovered. I have long thought that a more thorough exploration of these veins in depth might result in happy surprises. It should be recognized that the type of vein herein described differs materially from the lead-silver deposits referred to by Mr. Rickard as occurring in the Hautes Alpes, France, though this fact may have no material bearing on the question under discussion. The gold-bearing quartz lenses of the Julian district are similar to those found in Madera county, California; those in the central and southern Black Hills of South Dakota, some of those in the southern Appalachian States, and in many other localities, and are uniformly due to the silicification of crumpled schist and slate, and not to fractures which would tend to produce fissure veins rather than a succession of lenses of relatively limited extent.

It is interesting to note that in this district, as well as in others to which I have previously referred, ore-shoots do not cross gulches or depressions at the surface. One noticeable instance was in the Helvetia mine, where a rich shoot of ore occurred on the crest of the ridge, but where the vein crossed the gulch, although quartz occurred, it was valueless.

Berkeley, California, April 9. W. H. Storms.

Blue-Print Filing-Case

The disposal of blue-prints so that they are readily accessible but not in the way is hard to secure. The best way is to use the filing cabinets manufactured for this purpose, but a less expensive substitute can be made from an ordinary box, which should be about 40 in. high, 32 in. wide, and 12 to 15 in. from front to rear. Inside and a few inches below the top, 1-in. strips are fastened to the sides to support light wooden rods. From each pair of rods there depends a bag made of heavy manila paper; for convenience this is usually open down the sides to within a foot of the bottom. Blue-prints, drawings, or maps up to 30 by 36 in. can thus be conveniently kept flat and readily accessible. For convenience of reference the bags should be numbered, and an index can be kept pasted on the lid of the box, so that any required map can be quickly found. To keep blue-prints and drawings in this way they must be flat; maps that have been rolled can usually be flattened by rolling them the other way, while blue-prints can be effectually flattened by soaking them in water and allowing them to dry flat. Drawings of the same size should be kept together. Such a box will hold a dozen or more bags. Maps and blue-prints can also be kept flat in large drawers, but this takes up too much floor space, and if there are more than a few maps in a drawer it is difficult to remove those beneath and the edges quickly get dog-eared.

Special Correspondence

MEXICO

West Coast Railroad Extension.—Progress at El Favor.—Annual Report of Amparo Co.—Work at the Pachuca Mills.—New Mill of Purisima Grande.—Oil in West Coast Territory.

In order to facilitate shipments to and from mines in the Hostotipaquillo district of Jalisco, the Southern Pacific will at once extend the Jalisco line of its West Coast extension to La Quemada, nine miles beyond the present terminus. Arrangements for the extension were made through correspondence between W. C. Brown, president of the New York Central railroad, who is interested in the El Favor properties in that district, and Mr. Lovett, president of the Southern Pacific. The distance from La Quemada to El Favor and adjacent mines is about twelve miles. The El Favor mill, which recently started work, is handling 80 tons per day, and with two additional tube-mills, now being erected, the plant will be able to handle at least 125 tons per day. In March the Casados mine of the Consolidated Mining Co. shipped ore to the value of ₱25,000, and the April returns will exceed those of March. The Casados ore-shoot has been opened for a length of 1000 ft., and the indications are that it will prove to be fully 2000 ft. long. All ore shipped is from development. The 150-ton reduction unit, now under construction at Casados, will be in operation before the end of the year. The annual report of the Amparo Mining Co., of Philadelphia, operating in the Etzatlan district of Jalisco, shows a production of ₱1,439,665 from 68,217 tons of ore. The operating expense in 1910 reached ₱822,896. The net profit for the year, after a 10% depreciation charge, was ₱563,054. Net returns from the company's store and ranch raised the net income to ₱596,905. The company paid 12% on a capital of $2,000,000. A big reduction in operating expenses will be shown this year, due to the fact that the company is now using electric power for its operation.

Up to this time operations in the important Pachuca district have not been affected by the political disturbances in the Republic, but precautions have been taken against interference, the mining companies having armed men to protect property. The Real del Monte y Pachuca is following its program of enlargement and betterment, and as soon as all additional equipment is in place at the Guerrero plant it will be able to mill 1350 tons of ore daily. The Real del Monte y Pachuca is the first in production among the enterprises controlled by the U. S. Smelting, Refining & Mining Co. The new 600-ton plant of the Santa Gertrudis (Camp Bird) will be soon in commission, materially increasing the output of the district. The Guadalupe plant of the Santa Gertrudis, built by the former owners at a point about 2½ miles from the Santa Gertrudis mines, has been in operation for over a year, treating low-grade ore principally. The Purisima Grande y Guadalupe Co. has added a modern 100-ton plant to the reduction works of the district, and is supplying ore from its Guadalupe-Fresnillo mines. The new plant takes the place of the old Purisima Grande reduction works. The Encino y Anexas Co. has commenced deliveries to the La Luz mill under a contract calling for 1000 tons per week. The La Luz plant is being operated under lease by the Blaisdell-Cosecotitlan Syndicate, of Los Angeles, Cal., which for several years has been cyaniding the old tailing of the Pachuca district. Reports of the San Rafael y Anexas and La Blanca companies show excellent results.

The West Coast Oil Co., in which English capital is largely invested, has begun oil exploration work in Sonora. The scene of operation is near Mascareñas, a station on the Nogales-Cananea line of the Southern Pacific. Much interest attaches to the work, as the development of oil in the West Coast territory would mean much to that section of Mexico. The Mexican Petroleum Co., Ltd., has announced that it will omit dividend payments on its common stock for six months or a year, using the money for development. The company paid its first common-stock dividend last year, having been enabled to do so by the earnings of the Huasteca Petroleum Co., one of its subsidiary concerns. The disbursement was at the rate of $298,000 a quarter.

THE COEUR D'ALENE, IDAHO

Gross Proceeds, Costs, and Net Profits of Ten Leading Mines.—The Proposal to Assess Property at Cash Value.

In accordance with the laws of Idaho, the mining companies operating in the State filed with the county assessors, on May 1, a statement showing the tonnage of ore extracted, gross values of metals recovered, costs of extraction, reduction, and transportation, and the net profits for the year ended on that date. The statements given by the companies operating ten of the largest mines of the Coeur d'Alene district, Shoshone county, are especially interesting, a résumé of which is presented below:

Bunker Hill & Sullivan—Ore mined, 425,160 tons; gross

Map of the Coeur d'Alene.

yield, $3,514,431; cost of mining, $1,023,094; costs of reduction, transportation, and sale, $1,350,205; net profits, $971,263.

The Hercules—Ore extracted, 25,765 tons; gross yield, $1,249,081; costs of mining, transportation, reduction, and sale, $516,546; expended for new equipment and repairs, $313,992; net profits, $418,542. The new mill, built for the Hercules during the winter, is now finished and in operation.

Federal Mining & Smelting Co.—Wardner mines: Ore extracted, 191,500 tons; gross yield, $1,765,188; costs of mining, reduction, transportation, and marketing, $1,523,885; net profits, $235,303. Mace mines: Ore mined, 201,350 tons; gross yield, $1,852,282; costs, $1,358,893; net profit, $493,439. Morning mine: Ore extracted, 333,900 tons; gross yield, $1,203,013; net loss, $40,799.

The Stewart M. Co.—Ore extracted, 55,347 tons; gross yield, $327,790; cost of mining, $113,582; transportation, $13,933; smelter charges and freight, $108,221; reduction, $29,373; betterments and repairs, $40,891; total costs, $306,001; net profits, $21,788.

Caledonia M. Co.—Ore mined, 8078 tons; gross returns, $479,307; cost of mining, $136,262; costs of transportation, reduction, and sale, $184,631; net profits, $165,597.

Success M. Co.—Zinc and lead ores mined, 8471 tons; gross yield, $134,955; costs of mining, reduction, and sale, $124,906; net profits, $10,049.

Hecla M. Co.—Ore extracted, 129,480 tons; gross proceeds, $950,848; cost of mining, $402,702; transportation, $320,899; betterments, $10,373; total costs, $733,939; net profits, $216,909.

Snowstorm M. Co.—Ore mined, 62,700 tons; gross returns, $676,076; mining costs, $164,288; reduction and transportation, $358,730; betterments, $33,380; total costs, $556,399; net profits, $119,676.

Recapitulation as to net profits: Bunker Hill & Sullican, $971,263; Hercules, $418,542; Federal mines, $728,742, less net loss of $40,799 at Morning mine, $687,943; Stewart, $21,788; Caledonia, $165,597; Success, $10,049; Hecla, $216,909; Snowstorm, $119,676. All the companies named operate concentrating plants except the Caledonia and the Snowstorm; the Stewart operates a leased mill.

The amount of net profits made by mine operators is required to be stated for the purpose of tax assessments. There is much discussion in Idaho concerning tax assessments on mining and other property by reason of the governor's instruction to tax officers to assess at full cash value as the law specifies. Heretofore assessments have varied in the different counties from 30 to 60% of the cash valuation. It is generally admitted that assessments in Shoshone county, where there is a vast amount of mining property, have been on a higher valuation than those of most of the agricultural counties, which makes the State tax for Shoshone disproportionately high. Certain rates of tax levy are fixed by statute, and if assessments on a cash valuation basis are carried out, school and certain other taxes will be abnormally high, as the State legislature failed to change the rates of levy in anticipation of the plan insisted on by the governor. The convening of the legislature in special session is being considered, that it may change the fixed levies so that taxes will be equitable if property is to be assessed at cash value.

LONDON

REPORT OF THE DUCKTOWN SULPHUR, COPPER & IRON CO.—LARGE INCREASE OF BUSINESS.—SUCCESSFUL WORKING AT TRONOH MINES.—VALUABLE PROPERTY.

One of the few American copper mines owned and directed in London is that belonging to the Ducktown Sulphur, Copper & Iron Co. Owing to the excellent work recently undertaken to save sulphur and thus conform with modern requirements as regards the prevention of the escape of sulphurous gases, this company has attracted some attention, and though overshadowed as regards output by its greater neighbor, the Tennessee, it is probable that the technological methods are just as good. The latest financial details of the company will therefore be of interest. The company was formed in London in 1891 and has paid dividends continuously. During the year 1910 a profit of £38,376 was made. Out of this £4000 was allowed for depreciation, £2792 was paid as debenture interest, £6000 has been placed to reserve, £18,814 has been paid as dividend on the ordinary shares, being 10% less income tax, and £5644 has been distributed on the founders' shares. The production during the year was 2200 tons of copper, obtained by smelting 128,583 tons of ore, as compared with 2446 tons from 140,504 tons produced during 1909. The production of sulphuric acid was 46,500 tons. Important alterations and additions to the furnaces and power-plant have been made during the year whereby the amount of copper and acid will be increased and the smelting cost reduced. The cost of these improvements will be about £50,000, which will be provided by the issue of further debentures. The new shaft at the Mary mine has been completed and it gives access to a large body of recently developed ore. The East Tennessee mine has been fully equipped and is now yielding regularly. The business of this company has grown so much during the last year or two that two additional directors have been elected to the board.

The Cornish capitalists nowadays prefer to put their money in Malay tin mines rather than into those of their own country. A few weeks ago I cited the Gopeng, which is giving large profits on a small outlay. Another example is the Tronoh, which has on its list of directors such well known Cornish names as C. V. Thomas and G. B. Pearce. This mine had an interlude of adversity in 1907 to 1909, due to the incapacity, or worse, of the local directors. Some particulars will be of interest. The mine was introduced in England by Foo Choo Choon and E. G. Edgar in 1901, who continued to direct operations on the spot. For some years large profits were made, and from 1902 to 1907, £244,000 was distributed as dividends on a capital of £160,000. The tin is found in gravels of which some are on the surface and others in the form of deep leads. The mining was easy enough at first, but as time went on conditions altered and the local directors were not capable of meeting the difficulties. Another engineer was sent out from England, but did no better, and finally, three years ago, Harry D. Griffiths was appointed. He made certain recommendations for rearranging the work, and the directors consulted R. J. Freeheville before finally accepting them. Mr. Freeheville agreed entirely with Mr. Griffiths' views. The report for the year 1910 now issued shows that Mr. Griffiths has done excellent work in every way and that the output and profit have strikingly increased. The production of tin concentrate was 2945 tons, as compared with 2158 tons in 1909 and 1712 tons in 1908. The amount of gravel treated was 410,777 cu. yd., as compared with 292,825 cu. yd. in 1909 and 156,366 cu. yd. in 1908. The price obtained for the concentrate averaged £92 per ton, as compared with £80½ in 1909 and £72¼ in 1908, and the total receipts were £271,304, as compared with £167,755 in 1909 and £123,683 in 1908. The yield per cubic yard under Mr. Griffiths' régimé is about one-half what it was five years ago, the reason being that the old method of working only the richer patches introduced the danger of speedy ruin. The profit for the year was £72,927, as compared with £38,774 in 1909, and the dividend was £56,000 or 35%, compared with £16,000 or 10% in 1909.

NEW YORK

CAUTION IN PORCUPINE INVESTMENT.—LITTLE INTEREST IN MEXICO.—SELLING OF NEVADA SHARES.—SILVER MINES EXPLORATION CO.—KIRKEGAARD.—FAVORABLE REPORT.—CAMP BIRD EXPANSION.—YUKON GOLD.

The mining situation in New York is peculiar. Everything for the time being is Porcupine, although as yet there is no market activity worth mentioning. The air is full of the stories of deals under way or just completed at figures that sound out of all reason, and, indeed, would be out of all reason were it not for the fact that only small cash payments down are ordinarily required. There have been some deals made, however, and others attempted, where large sums were paid or promised to claim-owners, with the result that prices demanded are so absurd that capital otherwise eager for the development of the new goldfield is halted. The overreaching, eager greed of the claim-owners is actually retarding the growth of the camp. The Eastern press is wisely sounding a note of caution, calling attention to the fact that only one or two properties have yet been demonstrated to be anything but mere surface showings, and the further fact that Porcupine is, if it is anything beyond a sensational surface showing, a low-grade camp that must have big development done on its orebodies and large expenditures made for milling plants before profit is possible. When property owners come down out of the clouds and get on a sane basis, there will evidently be plenty of money in the States as well as English capital available for development. The present standstill is in the nature of a protest against the option holders who are trying to take out large profits with no money invested.

One of the particular and peculiar reasons for the exclusive interest in Porcupine at the moment, is that it has the stage all to itself. Mexican mining projects are interesting just now only to those already involved, the ruling conditions there prohibiting the formation or projection of new enterprises. Coppers are without a market public, and evidently must remain so until the metal situation improves. The shrinkage in copper shares is tremendous, and the margin between earnings and dividends in many cases has become perilously narrow. In Goldfield stocks there is a little accumulation of the cheaper prospects and a very little trading in Goldfield Consolidated. In the latter there has been steady liquidation for many months, it being evident that some large holding is being turned into cash just as fast as the shares can be absorbed. In the Tonopahs there has been some heavy selling of Tonopah Mining. The principal market for the stock is in Philadelphia, and while traded in on the New York curb, it is not officially quoted there. Recently there was some heavy selling of the stock in New York which was not duplicated in Philadelphia. It was quite plain that the sales were made in New York simply to evade the quotations and the records of the sales.

Taking the situation as a whole, it is quite evident that if Porcupine does not succeed, it will not be because of any distraction of attention elsewhere. There are more real mine-makers getting into the camp all the time. The Silver Mines Exploration Co., which is the Lewisohn organization controlling Kerr Lake and Wettlaufer at Cobalt, has just taken over three claims just over the line in Deloro township and directly south of the Dome Mines. The consideration has not been made public, but it is understood that the Lewisohns have several months for development work before any cash payment is required. This appears to be one case in which sanity prevailed. One of the best known properties in the camp, the Kirkegaard ground, of 120 acres, has recently been financed in New York by interests connected with the Proprietary Mines Co. of America, the flotation being offered to the public and oversubscribed almost immediately. A comparatively few successful deals of this nature have given the prospectors and option holders such absurdly exaggerated ideas of values. It is needless to say that there is a small army of camp-followers ready to grind out promotions over night and keep the printing-presses running overtime the moment the public begins to buy stock certificates. Up to the present moment nine-tenths of the investors in Porcupine shares have bought odd lots of Hollinger and hundred-share lots of the best-known prospects.

While Cobalt continues to be persistently overlooked in favor of the new Canadian goldfield and the Cobalt stocks sold to provide grub-stakes for Porcupine prospectors, there are some facts regarding Cobalt that are very interesting. A. A. Cole, mining engineer for the Temiskaming & Northern Ontario Railway Commission, has just made a report on Cobalt in which he states that the ore reserves of that camp are larger than at any time heretofore, that $30,000,000 worth of ore can be measured up in Cobalt, and that the camp could mine for two years at its present rate if no new veins were opened. The question of ore reserve has always been the vital one for Cobalt, and this statement is decidedly a bull argument for the silver camp.

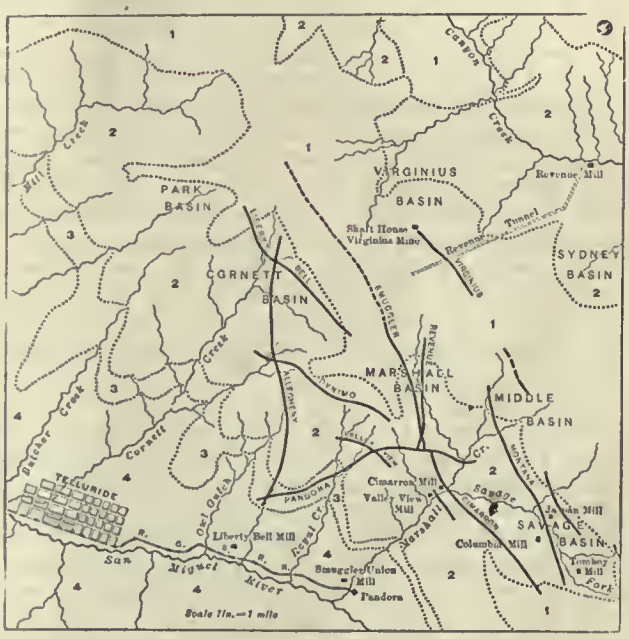
The Camp Bird shareholders in the East, of whom there is a large number, are much interested in the report that the company is negotiating for additional territory at Ouray, Colorado. An effort is being made to shape an option for the Camp Bird covering the ground owned by the San Pedro company. Control of the latter company lies with Terry & Tench, the great contracting firm. In addition, it is reported that the Camp Bird is probably to acquire the Revenue Virginius. Both properties adjoin the Camp Bird ground. The Revenue Virginius is owned by A. E. Reynolds of Denver and has a large production to its credit. On the Colorado property there is a large mill of the best type, and while the Revenue Virginius has been worked out on the original Virginius vein, it is said that what is practically a new mine has been made on the Montana vein. The San Pedro owns a large and practically unexplored territory. If either or both properties can furnish profitable ores to the Camp Bird mill, it will be a splendid move to acquire them. The Camp Bird has earned and is earning a steady profit from its present territory, but it has been recognized for a year and a half that the question of diminishing ore reserve was becoming of pressing importance. The Camp Bird, controlled by the Venture Corporation of London, owns the Santa Gertrudis in Mexico, which is expected soon to enter dividend ranks.

The Yukon Gold Co., the Alaska company of the Guggenheims, is said to have recently made some large purchases of mining property in the Yukon district on Gold Run creek and on Dominion creek. The consideration paid is said to have been more than half a million dollars.

SILVERTON, COLORADO

Renewed Activity.—Gold King Dividends.—Sunnyside Mill.—Fire at Frank Hough.—Development near Animas Forks.

The winter season in the territory tributary to Silverton has been a very dull one, but the coming of spring brings many signs of renewed activity and prospects of a more active season than for several years past. The stagnation of the past season was due to several causes, but was greatly



Sketch Map of Telluride District, Colorado.

increased by the shut-down of the Gold King, Hercules, and Silver Ledge mines and mills, all of which were producers and shippers during last summer and had promised to continue so for some years. The Gold King and Silver Ledge have been developed during the winter, a force of 30 men being employed at each mine, and both are now in a position to resume milling and shipping. The Silverton, Gladstone & Northerly railroad has been cleared of snow, and the King started to break ore on the 28th of April. This company intends to employ 200 men at the mine and mill, treating 300 tons of ore per day and shipping about 2000 tons of concentrate per month. The Gold King has paid over $1,300,000 in dividends, and it is claimed that the mine has now a two years' ore supply in sight at full mill-capacity. The Silver Ledge has large orebodies developed and will resume milling about June 1, at the rate of 200 tons of ore per day, producing 750 tons of concentrate per month. It is persistently rumored that the Hercules company will start development work soon, but there are no signs of activity at the plant as yet. This mine has been a steady producer at the rate of 100 tons per day for several years, but has been idle since February. The Terry estate, controlling the Sunnyside mine at Eureka,

will double the mill capacity at once. The present plant handles 80 tons per day and turns out 600 tons of concentrate per month. A local leasing company has applied for a lease on the Silver Lake mine, owned by the Garfield Smelting Co. This mine was purchased by the Guggenheims for $2,000,000, but has been idle for five years, except for small-scale operation by several local leasing companies. The new company, if granted the lease, proposes to sink the Titusville shaft to the next level, 150 ft., and drive both ways for about 200 ft., opening a block of ground that yielded a large amount of ore in the upper levels. The lessees expect to produce 100 tons of ore per day. The property of the Iowa Gold M. & M. Co., considered worked out in 1908, has been operated since August of that year by lessees who have produced over $500,000 and are at present milling 100 tons per day and shipping 400 tons of concentrate per month with at least a year's supply of ore. The Intersection mine is leased to local miners, and the 5-stamp mill is being operated steadily. The Gold Prince property at Animas Forks has been taken over by the bondholders and will probably be idle this year. This company owns the largest mill in the district, with a capacity of 500 tons per day, erected at a cost of $500,000, but the mine has never been able to supply that amount of ore. The property has been operated by a receiver for the past two summers, but has been unable to pay interest on the bonds and has passed into the possession of the bondholders. In February a disastrous fire destroyed the surface plant of the Frank Hough mine on Engineer mountain, and it is very doubtful whether it will be rebuilt. The underground workings are all in porphyry, which swells when wet, and it is probable that they have all been closed, as the shaft is now full of water. The Vermillion, at Animas Forks, will resume milling operations June 1, at the rate of 75 tons per day. This property is situated two miles above Animas Forks and cannot operate during the winter, as the water-supply freezes and the railroad is blocked by snow. Development has been carried on during the winter with a force of 12 men, and excellent orebodies are reported as exposed. The Columbus, in the same locality, has driven a new tunnel which cuts the vein 200 ft. below the old workings. This work has developed a large amount of milling ore, and it is expected that the company will build a mill in the near future. This mine has produced some excellent shipping ore from the upper workings. The Hamlet company, operating at Middleton, has voted to issue $150,000 in bonds for completing the lower adit which cuts the vein about 1400 ft. below the outcrop. The money will be used to develop the vein and to enlarge the present mill if the ore is as good as that found in the upper workings. In general, indications point to the best season for years, and with the return of capital to mining, the San Juan may be expected to occupy a prominent position among Western mining camps.

JOHANNESBURG, TRANSVAAL

ANNUAL MEETINGS.—PROGRESS AT CROWN MINES.—GOOD PROSPECTS.—FAR EAST RAND.—POOR SHOWING AND BAD GROUND.—RAND COLLIERIES.

During the past fortnight there have been many annual meetings of mining companies here, and when it is said that among them are included such concerns as the Crown Mines, Cinderella, Robinson, and many others, it will be readily understood that the fortnight's happenings have been of much interest. The only matter of regret in the report of the Crown Mines is that the working costs have gone up and the profits since the amalgamation have failed to come up to anticipations. When the extensive alterations and developments now in hand are completed the property should tell quite a different tale, because, whatever may be said to the contrary, the Crown Mines property will eventually be a striking example of amalgamation in its fullest sense, and not in name only, as has been the case hitherto with the various amalgamations which have so far taken place on the Rand.

Then there is the Cinderella Consolidated property, which promises to become the leading mine of the General Mining & Finance Corporation and one of the leading mines on the Rand. During the year the size of the property has been increased from 289 claims to 1719, and is expected to soon attain a total productive area of 2100 claims, representing a stretch of nearly three miles along the strike. The amalgamation scheme when carried out made £680,000 available for further shaft-sinking and development, while the amount available at the end of the financial year was £510,000. Since amalgamation with the adjoining properties a seven-compartment shaft 42 by 6 ft. inside the timbers has been commenced, and at the time of writing has attained a depth of 400 ft.; the permanent steel head-gear having been erected and electric hoists adopted; these are working well and not giving rise to the trouble and inconvenience feared in many quarters. It must not be overlooked that a single-shaft mine is already at work to a depth of nearly 5000 ft., and last financial year made a gross profit of £53,645 despite the drawbacks and limits placed on underground operations by law because of the mine having only one shaft. The working costs during the year have gone up 1s. 4d. per ton, owing to an accident, and expenses incidental to amalgamation, not to mention the fact that only 800 persons are allowed underground at one time, while the mine has only a single outlet. However, it is anticipated that a connection underground will be made with the Angelo Deep in about three months time, when all these restrictions will cease. It is clear from the remarks of the chairman of the company at the annual meeting that the mine is expected to take a leading position among the Rand's largest gold producers; by the end of the year the gold reserves will be increased to a million tons, and in three years time to four million tons. By the time the property is equipped and properly developed, an expenditure of one and a quarter million pounds sterling will have been incurred.

Properties in the area beyond Boksburg and known as the Far East Rand have been causing considerable uneasiness of late, owing to the unsatisfactory showing made in some cases, and in others to water troubles and bad ground encountered in sinking. Two mines and one shaft have already closed down, and, generally speaking, the progress made can not be considered satisfactory. This is much to be regretted, because this section of the Rand represents an area of several hundred square miles; one upon which a good deal of the future of the Rand will depend, as, practically speaking, it is quite undeveloped, having only three milling mines on its outcrop at Van Ryn. The annual meeting of the gold property known as the Rand Collieries, held during the week, at which it was announced that the options held over shares of the company at 45s. had not been exercised, that at the end of the year the available capital has been practically exhausted, is important. Of course when the shares of the company can be purchased on the open market at less than £1, those holding options at 45 and 50s. can scarcely be expected to exercise such options, and it is well that the control of the mine is in such excellent hands as the General Mining & Finance Corporation, otherwise it seems possible that the list of closed mines, waiting the advent of better financial times, might also include the Rand Collieries. Work is to go on as usual, despite the fact that a good deal of the development work done during the year shows values below 4 dwt., which today may be considered as the payable limit on the Rand. During the year no less than £142,320 was spent on equipment and development, the latter being more exploration than development, while the former includes excellent steel head-gears and up-to-date electric hoists, which here also are reported to give satisfaction. It is clear that even after such a large expenditure of working capital the Rand Collieries represents more a prospect than a proved mine, but with those in control of the property the shareholders have every confidence. Other mines in even a less promising condition than the Rand Collieries have by the same control been put on a sound dividend-paying basis.

General Mining News

ALASKA

Copper River

Enraged by the delay in development of the Alaska coalfields, a mob of 300 men stormed the stock-piles of Canadian coal owned by the Alaska Steamship Co. and the C. R. & N. W. railroad at Cordova, on May 4, and dumped the coal into the sea, as a protest against the use of foreign coal in Alaska while the native deposits remain undeveloped.

James Galen, who has returned from the Bonanza mine, says that 40 men are at work, the tramway is running regularly, and the railroad as well as the tramway, but a little trouble is expected when the ground thaws. The first shipment of ore made to the Tacoma Smelting Co. averaged a little more than 63% copper and over 17 oz. silver per ton. The ore is chalcocite. Fifty-five men are at work at the Great Northern Development Co. at Copper mountain, and it is planned to increase the number to 200.

A big ice jam in Copper river on May 7 tore out the wooden spans of the railroad bridge which was just completed last fall. The operation of the railroad and the shipping of copper ore from the Bonanza mine will be interrupted for a week at least.

Ketchikan

(Special Correspondence.)—The Alaska Industrial Co. of Sulzer has made seven shipments of ore since January 1. A new contract has been made with the A. S. & R. Co., which treats the ore at its Tacoma smelter. A small shipment of ore from the Goodrae mine is now on its way to the Tyee smelter. A. A. Wakefield, manager of the Gold Stream mine, is making ready to start the stamp-mill. Several hundred tons of ore is on the dump. Prospecting will not commence until May 15, because of the late spring.

Ketchikan, May 1.

The report last week of the snowslide at the Jumbo mine is correct. The two killed are F. T. Figg and John A. Tomasevich.

Prince William Sound

The adit on the Vancouver-Valdez M. Co.'s property is in 48 ft. on the vein, which is increasing in width. The adit on the Alameda group of claims on the east side of Valdez bay is in 30 ft. on a 12-ft. vein of quartz which assays $9.40 per ton. It is planned to erect a stamp-mill. The last clean-up at the Cliff mine yielded $6500. The new vein found recently has pinched, but assays as high as before; an adit has been driven on it for 25 ft. The cabins and power-plant belonging to S. A. Hemple, on Knight's island, were crushed by snowslides just before the beginning of April.

ARIZONA

Gila County

The fourth unit of the Miami mill was expected to start on May 10. Three are now in operation, treating more than 1400 tons per day. Over 50 tons of concentrate is being shipped daily. The auxiliary raise and sub-level method of stoping has been started by N. O. Lawton, the mine superintendent. The churn-drills on the Inspiration broke all records during April, the four doing 5093 ft., one machine making a record of 2600 ft. Most of the electrical equipment for the haulage system has been received. In the Live Oak the average ore found by the churn-drill runs 2.25% copper. Shaft No. 1 has reached a depth of 445 ft. and the blocking out of the ore has begun. Shaft No. 2 has reached a depth of 102 ft. The leaching plant of the Warrior Development Co. was burned on May 4, but, as it was not in use, the loss is not heavy. The company is shipping 100 to 125 tons of 10% ore per day. The vein found in the cross-cut on the 1000-ft. level of the Arizona Commercial shows glance and oxide. Drifts are being driven east and west on the vein.

Yavapai County

(Special Correspondence.)—Considerable alarm has been worked up around Jerome by the report that the United Verde smelter at that place was to be abandoned and all smelting for the great mine was to be done at Humboldt. It is proposed to build a railroad from Russell station on the U. V. & P. railroad to the smelter at Humboldt, thus saving a heavy haul over the mountains, and cutting out a piece of track on the U. V. road that is very heavy grade and hard to keep in repair. The big compressor for the Arkansas & Arizona company has arrived, the concrete foundation for it is prepared, and it will be put in place within the next few days. Development will be resumed about June 1. The machinery is being overhauled at the Haynes properties preparatory to resuming operations. The stockholders of the Venture Hill Mining Co. are holding a special meeting at Jerome to devise ways and means to resume work on their property. This is a most promising group of claims and should be prospected thoroughly.

Prescott, May 6.

CALIFORNIA

Amador County

The Utica M. Co. has appealed to the Supreme Court for a reversal of the judgment of $54,000 which the Lightner M. Co. recently obtained against it for wrongful extraction of ore, on the ground that an action for trespass is outlawed three years after the trespass was committed. It is probable that the Supreme Court will reverse the verdict of the lower court. Roy Cameron has been endeavoring to reorganize the miners' union at Jackson which went to pieces a year ago, and is meeting with moderate success. C. D. Lane has transferred a one-third interest in the Plymouth Con. Min. Co. to the Lane Investment Co., and the mine will shortly be re-opened.

(Special Correspondence.)—Regular monthly dividends of 7c. are being declared by the South Eureka, and it is rumored that the rate may be increased to 10c. within a short time. At the Central Eureka the management expects to commence the payment of dividends before the close of the year. Although electrical machinery was installed and other heavy expenses incurred, the year's operations left a good profit to the company. At the Lincoln Con. sinking is progressing rapidly. On the 800-ft. level promising stringers of quartz have been found in the cross-cut. It is reported that the Bunker Hill company is about to increase its dividend rate from 5 to 7½c. per month. Pocket mining in Murphy's gulch is attracting considerable attention. Several prospectors report satisfactory results. The Little Amador company has replaced its mule-team by a 5-ton auto truck. Developments at the mine are said to be extremely satisfactory. W. T. Deaner is superintendent.

Jackson, April 29.

Kern County

The Laird mine has a 6-stamp mill in operation in the Sageland district on free-milling ore that runs about $5 per ton. It is operated by the Laird brothers, who have recently made a good clean-up. J. J. Miller and the Watchman brothers have dissolved their working partnership in the King Solomon mine, and recently milled a lot of ore that went over $240 per ton. The shaft on the property will be sunk 100 ft. in depth in the near future. The Merced mine, owned by the Merced Min. Co., has been sold to T. W. Atkinson, who owns the Sunshine mine, but the price has not been given out. The development amounts to 1500 ft., and last year the lessees milled $6000 worth of ore. C. A. Burcham has taken an option on the William R. mine for $15,000. This mine was opened in 1909 and a 2-ft. vein has been developed which yields $45 ore.

Nevada County

W. H. Norton has made a location on the old burying-ground near the county hospital. It therefore is not improbable that his mine will turn out to be a dead one. The first payment of $10,000 on the Cassidy mine has been made by the Cassidy Con. G. M. Co. A strong shoot of $20 ore

was recently found on the 350-ft. level. It is proposed that the Arctic mine shall advance $6000 to the county supervisors to construct a new road from the mine on Canyon creek to the Maybert road, with the understanding that this sum shall be refunded when the company has developed its mine to a valuation of $50,000, but no decision has been reached by the county authorities. The Nevada County Deep Drainage Tunnel Co. has been formed to drive a drainage adit from the South Yuba river, near Jones bar, for three miles toward the Champion mine, where it will drain the district to a depth of 1050 ft. G. W. Starr and T. J. Hooper have taken charge of the Pennsylvania and W. Y. O. D. mines, and it is reported that the transfer of these mines to the California Title & Insurance Co. has

MOUNTAINEER MINE, NEVADA COUNTY.

been perfected. The Union Hill has been unwatered to the 350-ft. level and it is expected to start the 20-stamp mill soon. Arthur W. Hoge was elected president at the annual meeting of the Fairview G. M. Co. The 20-stamp mill, a few miles above Washington, which was damaged by snow last winter, is being repaired.

PLUMAS COUNTY

Charles Schoenwald, while at work cutting away a gravel bank in the Carter mine in East Indian valley, was caught in a slide of snow and earth and drowned by the backing up of the water. The annual meeting of the Haskell Peak M. Co., whose property is situated near Clio, was held recently. J. J. Snyder was elected president and Henry Goering superintendent; the former board of directors were all re-elected.

SHASTA COUNTY

The Mt. Shasta mine, near the old town of Shasta, has been bonded to Theodore Burkhardt of Portland for $50,000, and an initial payment of $5000 has been made. The mine is now owned by the Bank of Shasta County, which foreclosed a mortgage on it that was given by the owners in 1903 when the mine made good profits that were promptly lost in Arizona speculations. It is also reported that the Bully Hill Cave Co., which has been exploring the Michigan mines near Bully Hill, will take up its option and pay over the $100,000 of its bond to the bank. This mine, like the former, was owned by the Phoenix Securities Co. The Mammoth Copper Co. will reopen the Original Quartz Hill mine, near Old Diggings, to supply flux for its smelter at Kennett.

SOLANO COUNTY

Judge Buckles has refused to set aside the order of the Superior Court directing the officers of the Selby Smelting & Lead Co. to appear and show cause why they should not be judged in contempt of court for violating the injunction issued several years ago. The hearing has been set for June 6. The Selby company claims that it is not violating the terms of the injunction.

TRINITY COUNTY

T. Williams and L. Yancey, who last winter took a lease on the Meader property on Trinity river, near the old New York House, have found some good bunch ore that assays from $40 to $100 per ton.

YUBA COUNTY

The gold dredge recently launched at Hammonton, twelve miles east of Marysville, is the largest yet constructed. Its hull is 240 ft. long and its stacker 138 ft., with a displacement of 1600 tons, about double the ordinary dredge. It has a capacity of 300,000 cu. yd. monthly, and can work to an unusual depth. J. C. Campbell has purchased another pump to hasten the work of pumping out the Pennsylvania mine, and expects to be able to resume development work within ten days. A deal is on foot to bond the property to Eastern capitalists.

COLORADO

GILPIN COUNTY

The Anchor mine, in the Russell district, which is operated by the North American company, is shipping 25 tons per day from a 3½-ft. vein on the 400 and 500-ft. levels. M. Daniels is in charge. The Consolidated Mining Co. is getting the shaft-buildings and machinery of the old Concrete mine in shape preparatory to thorough exploration. C. E. Major is manager. The Running Lode mine has resumed operation and a large output is expected to be secured soon. The shaft at the Pillsbury has reached the 1000-ft. point and a sump is being cut at the bottom. William Auger is superintendent. Shaft-sinking at the Chase mine makes satisfactory progress, and H. Willis, the superintendent, has kept the cost down to $13.50 per foot.

TELLER COUNTY (CRIPPLE CREEK)

The Vindicator Con. G. M. Co. has bought the control of the Christmas G. M. Co., which it recently sued for $75,000 for wrongful extraction of ore. The transfer will end the lawsuit. The April production from the main shaft of the Mary McKinney mine on Raven hill was only 8 cars of from $20 to $50 ore, as the lessees have cleaned up and the shaft is only being operated on company account. Mr. Buckles, the superintendent, is now sinking a winze in ore from the 700-ft. level. The production made by lessees and the company from the Lee shaft of the Isabella Mines Co. was about 1000 tons of an average value of $25 per ton. The Ajax mine on Battle mountain shipped 1350 tons of $20 ore during April. The Little Giant M. & M. Co. in Pony gulch expects to have its mill in operation within two months, as soon as the present overhauling is completed.

(Special Correspondence.)—The results so far from the Roosevelt deep drainage adit have not been up to the expectations of most of the people directly interested. The total flow obtained when work was suspended was about 7500 gal. per minute. This was about March 17. Since that time the flow has gradually diminished to about 6000 gal. per minute. The average subsidence of the water over the area drained is probably 35 to 36 ft. During the month of April the average subsidence was approximately 6 ft., or a little less than during the preceding month. The total underground or storage water may be estimated to be about 40,000,000 gal. per vertical foot. It was expected that a much larger flow would be obtained in the Beacon Hill water course, and that the subsidence of the water over a large part of the district would be 10 to 12 ft. per month. In this respect disappointment has been experienced, but nevertheless the enterprise can not be considered unsuccessful, as some claim. It is draining the district. The funds of the tunnel company have been exhausted, but efforts are now being made to raise an additional $50,000 to extend the tunnel to other known water courses in the hope of increasing the total flow and lowering the water more rapidly. This will probably be done in the near future.

Cripple Creek, May 6.

IDAHO

SHOSHONE COUNTY

(Special Correspondence.) — The concentrates being shipped from the Murray district of the Coeur D'Alene amount to 500 tons per month, about 90% of which is supplied by the Monarch mine and mill, owned by the Coeur D'Alene North Fork M. & S. Co. This company has increased the capacity of its mill and will soon be concentrating 200 tons of ore per day. The Monarch concentrate averages 60% lead, and contains 7 to 12 oz. silver per ton; a zinc middling is made, which is reconcentrated, the product being 45% zinc, and 3 to 6% lead. The other prop-

erties from which concentrates are shipped consist of the Black Horse and Terrible-Edith, though the Bear Top mill is reported about ready to operate and when it gets to working at full capacity the concentrate shipments will amount to 8 to 10 carloads per month. Considerable crude ore is being hauled to Eagle station from the Jack Waite mine, which samples about 70% lead and 7 oz. silver. This consists of steel galena. This mine is situated at the head of Tributary creek, 12 miles from Eagle, and it is probable that the Idaho Northern Railroad Co. will build a spur to a place within three miles of the mine.

Murray, May 2.

(Special Correspondence.)—The Snowstorm Mining Co., which operates the Snowstorm copper mine, situated two miles east of Mullan, is shipping 200 tons of ore that samples 4 to 4½% copper, less than 3% iron, and 1 to 2% sulphur, and 90% silica. As this ore runs high in silica it is in demand for use as converter lining, and the company's shipments are made to various smelters. The mine is situated about a mile from the Northern Pacific railroad at Larson station, and an aerial tramway of that length serves to convey the ore from the No. 3 adit to the shipping bins. Most of the ore now extracted is taken from the stopes between adits No. 3 and No. 2. Adit No. 4, several hundred feet below No. 3, has been driven to the ore zone, and it is probable that eventually this may become the main haulage-level. This is the only copper mine in the Coeur d'Alene.

Larson, May 4.

(Special Correspondence.)—The ore-shoot opened in the Hecla mine, on the 1200-ft. level, is identical with the shoot opened on higher levels, and is stated by Jas. F. McCarthy, the manager, to be of about the same width, and to contain ore of similar grade, as existed in the upper levels. The drift started in ore some time ago at the 1200-ft. level has been advanced three-fourths of the length of the shoot. The shaft, now having a depth of 1200 ft., is to be sunk to the 1500-ft. point. Two 425-gal. electric-driven pumps have been set at the 1200-ft. station, and these are required to raise 300 to 600 gal. of water per minute. The mine is opened by levels from the 300, 600, 900, 1000, and 1200-ft. stations, and by levels 100 and 200, which are adits. The Hecla company is shipping about 1050 tons per month of concentrate, and 550 tons of hand-sorted crude ore. This concentrate product results from the milling of over 8000 tons of ore per month.

Burke, May 5.

(Special Correspondence.)—The Gold Hunter Mining & Smelting Co., operating at Mullan, is mining and milling 300 tons of ore per day, and with the additional equipment being put in this will be increased to 450 tons. This ore, which runs 10 to 12% lead, and 16 to 21 oz. silver per ton, is being mined on the two parallel veins, between adit-levels No. 5 and 6. These veins are about 100 ft. apart on No. 5 level, and occur in quartzite. No. 6 adit, part way a cross-cut, has a length of 4300 ft. At a point 3600 ft. from the portal a 3-compartment winze has been sunk to a depth of 200 ft. about midway between the two veins. A station was cut at the bottom of the winze, and from it a cross-cut was driven to the south vein, said to be 8 to 40 ft. wide, and containing ore running 22% lead and 32 oz. silver. The north vein is to be similarly opened at this depth. An Ottumwa double-drum electric hoist is being put in place at the collar of the winze, and as soon as it is ready for service, sinking is to be resumed, with the intention of continuing to a depth of 800 ft. Much of the ore opened by the winze is considered of shipping grade, and a sorting plant is being built at the mill for separating the high-grade from the mill ore. Dennis Ryan is the company's manager, with T. M. Brennan as superintendent.

Mullan, May 5.

MONTANA

Chouteau County

The King & Queen mine, on Spring gulch, near Carter, which was originally located in 1887 by John Cromie of Spokane, and is now controlled by a Pittsburg syndicate, is arranging to ship a car of the ore recently found on the 300-ft. level. A winze, sunk 50 ft., shows high-grade galena all the way, as high as 40% in lead and 60 oz. of silver per ton. The outlook is so promising that the Chicago, Milwaukee & Puget Sound will build a spur to the mouth of the gulch, reducing the wagon haul to three miles. The mine netted more than $50,000 from ore in the upper workings, where the showing was from 4 to 10% copper, with a small percentage of lead.

Fergus County

The Cumberland mine and mill, at Maiden, in Judith basin, are operating successfully and paying a profit of $10,000 to $15,000 per month. The mill and cyanide plant, now having the capacity of 200 tons of ore per day, are being operated on ore that runs $6 per ton. The cost of mining and treatment has been reduced to about $2.50 per ton. The property belongs to James Breen of Spokane.

Madison County

The property owned by J. M. Vineyard in Bear gulch, not far from Twin Bridges, is showing up well in the long adit and gives assays of $12 to $18 in gold. The vein is of good size. The new dredge of the Conrey Placer company in Ruby valley was started in operation the other day. It is the largest in the world working at a placer property, and cost $250,000. The dredge digs 55 ft. below the waterline.

Silverbow County

(Special Correspondence.)—W. A. Clark recently visited Butte, and has made arrangements for enlarging and remodeling the Butte Reduction Works so that the zinc ore from the Elm Orlu mine may be treated more economically. The Corbin Metals Co. has paid the final installment of $20,000 on its property at Corbin. A 500-ft. shaft has been sunk and good ore uncovered. The Butte & Superior is shipping 450 tons per day to the mill, which saves 78% of the zinc content of the ore, making a concentrate that carries about 50% zinc. The general run of the ore in the mine averages 20% zinc, while some rich ore goes as high as 60% zinc. In the Butte-Alex Scott a new 6-ft. orebody has been found on the 500-ft. level. The company is shipping two cars per day of ore that nets $850 to $950 per car, as it carries 5 oz. silver and 7% copper per ton. At the Mountain View mine the new hoist, operated by compressed air, is now in use. The compressed-air plant is operated by electricity supplied from the Great Falls power-plant, and the hoisting plant derives interest from the fact that it is the largest of its kind in America. The machinery was specially built for this plant by the Nordberg Mfg. Co., and has given such satisfactory service that the Diamond mine will next be similarly equipped. The saving in the cost of power will amount to 1c. per lb. of copper.

Butte, May 5.

NEVADA

Esmeralda County

The preliminary estimate of the April production of the Goldfield Con., made by J. F. Thorn, superintendent, shows that approximately 28,253 tons of ore was handled during the month, the gross recovery being $964,000; costs, $210,000; net profit, $745,000. These figures will be revised in making out the regular monthly statement. This brings the total gross earnings of the company for the first four months of the year to $3,740,616, from which net profits of $2,972,245 have been obtained.

Lincoln County

There are more mines now at work in the Pioche district than at any time during 1910. The Day mine of the Nevada-Utah is shipping 100 tons per day and it is stated that it has 40,000 tons of ore blocked out; the condition of the property is excellent. At the Mendha Nevada a winze has been sunk in ore for 50 ft. below the 900-ft. level. M. C. Godbe, manager of the Eastern Prince and Centennial Pioche, reports that good ore has been found in the latter. At the former good progress is being made in shaft-sinking. Good ore is being found in the Demijohn, where development work is in progress.

Nye County

(Special Correspondence.)—The Ferguson lease on Union No. 4 is reported to have opened a streak of high-grade ore. The tunnel at the White Caps has cut 2 ft. of ore reported to assay $75 to $100 per ton. It is reported that operations will be shortly resumed at the Breyfogle. Zeh Kendall has taken a lease on the Joker estate lying east of Big Four. The March yield of the Johnnie Con. mine at Johnnie amounted to $11,842.79, produced from 2000 tons of ore. The total expenses were $10,575.13, leaving a profit of $1767.66. During the month 650 ft. of new development was accomplishment, an extra shift having gone on. Ore is being produced from the 500, 600, and 800-ft. levels. Mining costs have been brought down to $1.50 per ton, development $2, crushing 16c., and milling $1.47. A large feature of the cost is the power and transportation items, the distance of the property from the railroad and the consumption of distillate for fuel reacting against greater economy. J. K. Turner is consulting engineer, and Jerry Rourke superintendent.

Manhattan, May 5.

The Sandstorm-Kendall has sent out a special report showing the receipts from assessment No. 2 and the disbursements for exploration and other purposes. The annual report of the Belmont shows that during the year 21,900 tons of ore was sent to the smelter and 59,159 tons milled, the average value being $34.93 per ton. The gross earnings were $2,314,205, the cost of operation, including depreciation, $811,824, incidental earnings were $19,920, making a total profit of $1,522,301. The individual surplus amounts to $1,185,867. The ore reserve is estimated as 260,324 tons of positive ore and 182,714 tons of probable ore, of an average value of $26 per ton.

White Pine County

(Special Correspondence.)—The Giroux company is finishing its surface plant which it has been engaged in constructing for nearly two years. The property is being developed on the 700, 1000, 1200, and 1400-ft. levels. The cross-cuts from the Giroux shaft to the old Alpha workings on the 1200 and 1400-ft. levels are progressing rapidly. The 1200-ft. cross-cut will reach the Alpha workings in a few weeks, after which the shipping of direct smelting ore to the Tooele smelter will be started, although no announcement has as yet been made to that effect by the management. It is not expected, however, that any effort will be made at stoping out ore, but that taken out in development work will be shipped. It is expected that the churn-drills will soon be started up again on the sulphide deposits. They were out of commission all winter, owing to the scarcity of water, due to the freezing of the streams. From present indications there will be no erection of plant by the Giroux company during the present year. The management is devoting its principal energy to developing high-grade orebodies along the lime contact. Developments at Boston Ely are progressing steadily on the 1245-ft. level. The contact was reached last month by the west cross-cut but no ore was found at that point.

Ely, May 6.

During April the Nevada Con. shipped 5008 cars of ore to the Steptoe mill, a total of 279,000 tons. The largest amount handled in one day was 9300 tons. Eight sections of the mill are now in operation and the production is expected to further increase.

Recent reports from Duck creek are to the effect that very good ore is being found in the Lead King, on the east side of the range and in the Ely Gibraltar on the west side, and the prospects of developing a lead-mining camp at that place are very bright.

OREGON

Baker County

The Rainbow gold mine, situated in Mormon basin, 35 miles southwest of Baker City, has passed to the United States Smelting, Refining & Mining Co., at a price announced to be $750,000, of which $200,000 is said to have been paid. The vendor was the Commercial M. Co., which gave the purchasing company an option several months ago. The mine was opened about eight years ago, since which time it has been well developed and equipped with a mill. During the first five years W. E. King, a stockholder in the company, directed operations. More recently, H. C. Wilmot has been in charge. It is reported that A. P. Anderson and H. S. Lee have taken charge of the property for the purchaser, and that the scale of operations is to be enlarged. The Humboldt mine and mill, also situated in this basin, belong to the Oregon-Idaho Investment Co. It is a promising property. Mormon basin is in the vicinity of the old Malheur camp, where there was formerly considerable placer mining and cyaniding of gold ore. The nearest railroad station is Durkee, situated half way between Baker and Huntington.

UTAH

Beaver County

(Special Correspondence.)—The Copper Mountain property in the Beaver Lake district will begin shipping soon. The South Utah Mines Co. is planning to build a dry concentrator.

Newhouse, May 5.

Juab County

(Special Correspondence.)—The King William company at Eureka has stopped work pending a survey through Grand Central ground to give them a better idea of where to find the ore in their own ground. Tintic shipments were 141 cars for the week ended May 5, as against 166 cars for the previous week. Iron Blossom shipped 23 cars to Centennial Eureka's 28. The rumor that the decreased shipments of the Iron Blossom were due to caving of its stopes is declared to be without foundation by the management.

Mammoth, May 6.

Salt Lake County

The annual report of the United States Smelting, Refining & Mining Co., just issued, gives the following figures of its metal production for the last three years:

	1910.	1909.	1908.
Copper, lb.	28,430,425	36,672,606	32,830,603
Lead, lb.	51,450,985	41,627,995	27,304,347
Silver, oz.	10,776,465	9,637,119	8,340,566
Gold, oz.	113,246	128,393	128,208

The financial statement for 1910 and the year preceding is as follows:

	1910.	1909.
Earnings of all companies after all charges but depreciation	$3,738,540	$4,155,012
Depreciation	1,067,068	810,247
Administration, legal expenses	187,154	198,404
Interest on U. S. Mining 6% bonds.	.....	10.000
Profit for year	2,484,318	3,136,360
Undistributed surplus previous balance sheet	1,715,230	987,704
Total	$4,199,548	$4,124,064

From the profit for the year $1,701,700 has been paid as a dividend on the preferred stock, $702,100 in dividends on the common stock, $852 in dividends to minority of sub-companies, leaving an undistributed surplus of $1,794,895.

Summit County

(Special Correspondence.)—The American Flag has encountered on the 700-ft. level the rich vein developed in the old adit workings. It is now driving for this vein on the 100-ft. level. The Daly-West company, in accordance with contract, has driven its drainage adit to the Thompson-Quincy Consolidated company's lines, and the latter company will now continue the work into its own property.

Wasatch, May 6.

The Daly Judge and Daly-West mills have adopted the 8-hr. shift plan without the workmen having made any demand for it. The new arrangement went into operation on April 26.

WASHINGTON

Ferry County

The McKinley Mining Co. has engaged C. W. H. Swanson as consulting engineer and superintendent of the property in the Orient district. P. Larson, of Spokane, secretary of the company, says the property will be developed extensively during the season, the plans calling for an adit below the first vein to drift on the orebody for 4500 ft. Twenty-two thousand dollars has been expended on underground work. The ore brought out to date ranges from $45 to $5 in gold. There are three veins which unite to form a large one. Mr. Swanson expects to have ore ready for cyaniding within five months and has recommended the erection of a $20,000 plant.

Stevens County

The Germania M. Co. is employing over 100 men at its tungsten mine, situated in Deer Trail camp, 25 miles west from Springdale. A concentrating mill is being operated. The mill product, consisting of concentrate running high in tungsten, is hauled to Springdale, and shipped to market. Other properties in that camp are being developed.

CANADA

British Columbia

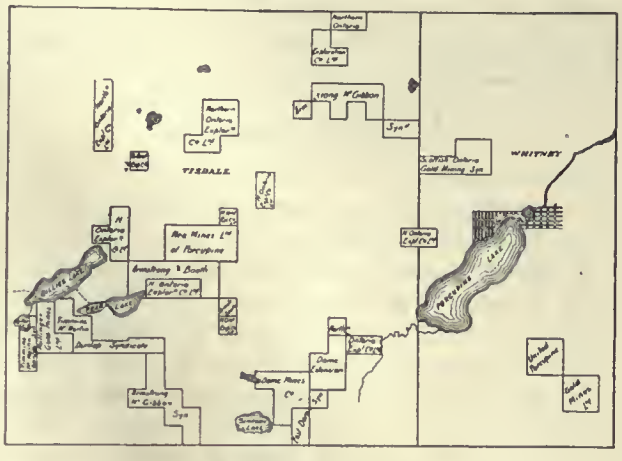
The Standard Silver-Lead M. Co., anticipates having its 100-ton concentrator ready to operate by August 15. The crushing and grinding machinery has a capacity of 200 tons per day, and it is possible that the concentrating equipment may be increased to that capacity in a year or two. The plant is being equipped with Harz jigs, Wilfley tables, and vanners, all machinery to be driven by water-power direct. It is estimated that 30% of the ore is of shipping grade. The principal metals are lead and silver; the small percentage of zinc associated with these metals is to be recovered by re-concentrating. The 8000-ft. tramway, extending from the mine to the mill-bins, is being constructed by the A. Leschen & Sons Rope Co. The mill-site is on Slocan lake, at Silverton, and the ore and concentrate are to be shipped by water.

The McKinley group of mineral claims, belonging to the McKinley Mines Co., situated in Franklin camp, forty miles north of Grand Forks, on the north fork of Kettle river, has been bonded to the British Columbia Copper Co. of Greenwood. The sum named in the bond is said to be $100,000, and the term is one year, during which time the latter company intends to develop the property extensively. The Kettle river branch of the Canadian Pacific Co., which now extends twenty miles up this stream from Grand Forks, may be built to Franklin camp if the McKinley and other groups prove to have large bodies of commercial ore as the result of development.

Members of the executive board of the Granby Con. Mining, Smelting & Power Co., accompanied by Jay P. Graves, general manager, William Yolen Williams, consulting engineer, W. A. Williams, smelter superintendent, O. B. Smith, mine superintendent, M. K. Rodgers of Seattle, and others, are visiting the Hidden Creek copper mine, on Observatory inlet, Portland Canal district, which was taken under bond by the Granby company last November. The property was considerably developed prior to the time the bond was given, and since then the Granby company has had development in progress with a good force of miners, and exploration by diamond-drills has been carried on. Hidden Creek ore is said to sample 2½% copper as a fair average.

Ontario (Cobalt and Porcupine)

Another gold discovery has been reported from Mt. Sinclair, in the Matachewan country, midway between Porcupine and Elk lake. As soon as navigation opens prospectors will start for the new find. It is stated that early in this month a mixed passenger and freight train will be run to Frederickhouse Lake, on the Porcupine line. On the Porcupine Imperial in Deloro a wide quartz vein carrying $40 per ton has been found about 200 ft. from the main vein. The shaft is now down 75 ft. Frank Armstrong has bought the Watson syndicate claims in Tisdale township for $25,000. The temporary break in the service of the British-Canadian Power Co. has been repaired; there is now enough water in the storage reservoir so that a repetition of the water famine is impossible. Mr. Thompson, who has leased the Greene-Meehan, has found a 6-in. smaltite vein carrying native silver. It is reported that high-grade ore has been found at the end of a drift on the 72-ft. level on the Ophir Cobalt. Reports from the Cripple Creek camp continue to be very encouraging.



Map of Porcupine.

MEXICO

Chihuahua

The new pumps for the Apodaquena have arrived, and the transformers are expected soon. About 85 tons per day is the average rate of shipment from this property. In the El Rayo mine, Sta. Barbara, high-grade ore has been found in the northern part of the workings, 250 ft. below the rich find of last year. Carload samples have averaged $35 per ton. J. S. Colbath is manager. The conditions have been somewhat disturbed in Parral, but are quieting down and the mills are in operation.

Jalisco

The first clean-up of the El Favor M. Co. in the Hostotipaquillo district has been made. The concentrate runs about 6 gm. of silver per ton, representing 34½% of the metal in the ore, while 50% of the silver is recovered by the cyanide process. As soon as the two new tube-mills are at work, the 20-mesh screens on the stamp-batteries will be replaced by 8-mesh, and it is expected to raise the stamp-duty from 4 tons to 7 tons per stamp per day. The Casados mine, owned by the Con. Min. Co., shipped ore worth $25,000 during March, and the April production is expected to be greater. The work on the 150-ton mill is well in hand, and it is expected to be in operation before the end of the year. The hydro-electric plant of the Tajo mine in the San Sebastian district will be in operation before the end of the rainy season, and the 100-ton mill will then be started. Drifts on the Tajo vein have exposed ore running from 600 to 1400 gm. per ton.

Sonora

The first lot of concentrate received at Cananea from the Miami mill amounted to 300 tons. Five furnaces are again in operation and the new reverberatory furnace is giving satisfactory service. The March copper production was about 3,500,000 lb. The revolution has not interfered greatly with mining operations in Sonora. During March 243 tons of ore was passed through the customs house of Agua Prieta. But the Las Chispas and the Colorado mines have been obliged to shut down because of the revolutionary activity in their neighborhood. The 66-mile transmission line from Douglas, Arizona, to the El Tigre mine is completed with the exception of the span over the Yaqui river. The transformers have arrived and are at the mine, and it is expected that the new plant will be ready to start not later than June 15.

Personal

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

LEE FRASER is at Oruro, Bolivia.

E. B. KIRBY is in San Francisco.

J. HINES has gone to Cordova, Alaska.

GEORGE J. ROCKWELL is in San Francisco.

J. F. CALLBREATH, JR., is in San Francisco.

ALFRED VON DER ROPP has gone to London.

S. B. ELBERT was in San Francisco this week.

E. H. ALLEN sailed on the *Queen* for Dawson.

G. B. STREET has returned to Wilmington, Delaware.

W. E. THORNE left New York on May 4 for Denver.

E. H. BENJAMIN has gone to Hayden Hill, California.

G. F. KAY has been appointed State Geologist of Iowa.

A. A. BOOTH, of Spokane, was recently in Malheur county, Oregon.

LEWIS P. LARSON, of Spokane, is operating a mine at Metaline, Washington.

CHESTER F. LEE, of Seattle, is directing mining operations at Scott's Bar, California.

V. V. CLARK, of Seattle, was recently in New York. He is to be at Nome early in June.

A. I. GOODELL represents the International Smelting & Refining Co. in the Northwest.

COURTENAY DE KALB is examining the Castle Dome silver-lead mine in Yuma county, Arizona.

FERDINAND MCCANN has returned to San Sebastian, Jalisco, Mexico, from Hostotipaquillo.

W. A. KNOL, of Rotterdam, Holland, who was in San Francisco, has gone to Nevada and Utah.

T. J. JONES has gone to Russia to become mine manager for the Kyshtim Corporation, Ltd., at Karabash.

CHARLES F. SPAULDING has been appointed manager for the Veta Colorada M. & S. Co., at Parral, Mexico.

HAROLD JONES is assistant metallurgist to the St. John del Rey Gold Mining Co., Ltd., at Minas Geraes, Brazil.

R. W. HIGGINS is superintending the operations of the MacQuisten tube plant in the Morning mill, Mullan, Idaho.

C. C. O'Loughlin has taken charge of the assayers' supplies department of Stewart & Holmes Drug Co., Seattle.

J. POWER HUTCHINS and NORMAN C. STINES are drilling dredging ground on the Chusovaya river near Ekaterinburg, Ural Mountains, Russia.

JOHN R. MITCHELL, manager for the Gastineau Mining Co., owner of the Alaska-Perseverance mine, at Juneau, was at New York recently.

LIONEL LINDSAY is examining the Quintera mine at Alamos, Sonora, for Courtenay De Kalb of the Mexican-American Smelting & Refining Company.

E. H. WILSON, who with his associates purchased the Snowshoe mine, near Libby, Montana, is at the property making preparations to begin operations.

C. J. ADAMI, for the past four years superintendent of mines for the Federal Lead Co., has resigned and has been appointed assistant general manager for the Doe Run Lead Co. at River Mines, Missouri.

J. E. MCALLISTER has resigned as general manager for the British Columbia Copper Co., and will join a New York firm of mining engineers. He becomes consulting engineer for the British Columbia company. E. G. WARREN, former smelter superintendent, succeeds Mr. McAllister as general manager.

The SCHOOL OF MINES AND METALLURGY OF THE UNIVERSITY OF MISSOURI will hold its commencement exercises on May 26.

EDITORIAL

THE ADDRESS delivered to the mining students at Berkeley, California, by Mr. J. R. Finlay contains a message that should go to all young men entering the profession. We are glad to hear such good doctrine preached.

MINING machinery is not often exported from California to Germany, but at least one tube-mill is now on the way to Hamburg from San Francisco. This is an incidental result of the activity of the revolutionists at Mazatlan.

LOST HILLS now has an oil well that is a gusher, the Martin & Dudley well having 'come-in' last week. According to the *California Oil World*, the daily production of the four Kern county fields amounted to 118,748 barrels in April.

MASSACHUSETTS seems likely to take the lead in requiring full publicity of all mining corporations whose stock is offered for sale through any mining exchange or newspaper in the Commonwealth. An interesting provision is that on demand of 25 per cent of the stockholders, the management must permit the examination of the property by a mining engineer selected by those making the demand, and that half the expense of the examination shall be paid by the company. The bill has been favorably reported and seems likely to become a law.

IN an interesting address last week before the Finance Forum in New York, Mr. J. Parke Channing pointed out that it was the improved methods of treatment developed at the older mines which had made the porphyry copper deposits valuable. The hill at Butte he cited as practically a porphyry copper mine, though it is usual to think of it as something entirely different. Butte, however, has developed as a result of years of work in the immediate vicinity. At Miami, by spending $4,000,000 and four years time, a mine containing 20,000,000 tons of ore assaying 1½ to 3 per cent copper, has been developed. Here knowledge gained elsewhere has been applied, and in time engineers expect and will doubtless receive liberal contributions to technical science from Miami.

COMSTOCK shares have been increasingly active on the local exchange since the first of the year. The important discovery in the Mexican affords a valid reason for some increase in price of the leading stocks; but the legitimate rise was long since discounted. Monday last prices broke, as was to have been anticipated. With shares that are so completely in the hands of stock manipulators as are the Comstocks, it is always hazardous to make predictions, but on their merits prices should be still lower rather than higher. We have every confidence in the discovery along the Lode of additional bodies of ore that can be worked with profit, but Comstock history is one long record of disaster due to what is really gambling, with shares instead of chips as counters.

BONDING of the Mt. Andrew mine on the south side of Kasaan peninsua, Prince of Wales island, to the United States Smelting, Refining & Mining Company is announced. This calls attention again to the rapidity with which important mines are being developed in southeastern Alaska, as well as to the activity of the excellent company which rejoices in the all-inclusive name. A brief description of the Mt. Andrew mine was given in the *Mining and Scientific Press*, April 15. The deposit is large and may be cheaply worked.

GROSS misrepresentation is charged against the Hydro-Electric Mining Company by the State Mineralogist of California. Mr. F. W. Ford, president and general manager of the concern that proposed to obtain a bullion output of $1,460,000 per annum from the French Hill mines in Eldorado county, with "no tunnels, no shafts, no hoisting, no timbering, no pumping", has been arrested, and will have opportunity to prove in court a few of the glittering promises circulated by the company. False statements about mining properties are much less common than they were a dozen years ago, and we hope to see them made rarer still. We have no admiration for the present State Mineralogist of California, but are glad to commend his recent activity in prosecuting fraudulent promoters.

DECISION of the Standard Oil case by the United States Supreme Court was announced this week and, as has been true of the majority of the important recent decisions of the Court, the results seem somewhat mixed. Now that it is over, everyone wonders why business has so long hesitated for fear of a decision adverse to the company. Nominally the Government wins at almost every point, as was true in the case against the anthracite coal roads; actually it does not seem likely that any great revolution in business methods will result. In both instances the Court has laid down an admirable principle, but in the anthracite fields there is a close monopoly now as ever, and we doubt not that Standard Oil will serve reformers as the horrible example of a 'trust' for many years to come. Many see danger in the statement of the Court that the rule of reason must be used in measuring restraint of trade; that only unreasonable restraint is forbidden. We do not agree that this is a bad rule if it be but lived up to. The evil effects of forbidding any form of restraint of trade are apparent to all familiar with the coal situation in the Middle West. Coal, money, and men are yearly sacrificed because it is easy to open a coal mine and no agreement among operators is legal. The difficulty under the new rule will be to determine in each case what is reasonable and what is not. Approached honestly, it is not an insuperable difficulty; and the reward is worth the effort.

OFFICIAL ANNOUNCEMENT of the sale of the Risdon Iron Works at San Francisco to the United States Steel Corporation has been made, and it is also reported that options have been taken on the Moran shipyards at Seattle, as well as on terminal properties at Portland and other Coast points. The history of the Risdon works is the history of San Francisco. Established at Bush and Market streets in the early fifties by Lewis Coffey and John Risdon, two New York boiler-makers, the plant was later removed to Howard street near First, and at one time had the backing of the four 'bonanza kings', Mackay, Fair, Flood, and O'Brien. In the beginning it was only a blacksmith and boiler-shop, but grew rapidly until it took on the importance of an iron works and at one time during the Comstock excitement was known as the Risdon Iron & Locomotive Works. Only one locomotive was ever manufactured, and this part of the title was dropped upon removal of the plant to the Potrero at Twentieth and Kentucky streets. After the deaths of the original owners the plant became the property of Mr. William Taylor, a steamboat master, who, pleased at the excellent product of the works, bought an interest in them. At his death the ownership passed to his heirs. Messrs. Augustus and W. H. Taylor, his sons, signed the deed which gave ownership to the United States Steel Corporation. At one time the Risdon employed 1500 men and it has been noted for the excellent marine engines and other work turned out. The Risdon works have built much mining machinery, and designed and erected the first dredges used in California. In this line, especially, the company did pioneer work. Purchase by the Steel Corporation of the works follows activity on the part of men connected with it in examining and buying iron ore deposits, of which there are several of value in southern California. There is talk locally of erection of blast-furnaces, though nothing authoritative has been announced, and such a move is unlikely. All the city properties selected are notable for their excellent situation as regards receipt and re-shipment of freight, and it may well be that for the present the move means merely that the Corporation proposes to carry larger local stocks of iron and steel. This enlargement of the local activities of the greatest American business institution is the first tangible sign of the approaching completion of the Panama Canal.

Dredging in Russia and Siberia

Americans have an unusual interest in foreign gold-dredging fields. The heavy 'California type' dredge, developed here from the earlier and lighter New Zealand boats, has made phenomenal records in several of the States and has dominated the dredging industry in the Far North. At the same time the New Zealand type of boat had held almost undisputed sway in foreign countries. In Russia boats have been built on American lines, though nothing comparable to the 'dreadnaughts' recently erected in California by the Yuba Construction Company, and in Montana and the Yukon by the Marion Steam Shovel Company, is in use anywhere abroad. Modern American dredges were shipped last year to Colombia by the Yuba Construction Company, to Burma by the Bucyrus Company, and to Siberia by the New York Engineering Company. It is hoped that the success of these boats will lead to the building of many others. Americans find it hard to believe that conditions abroad differ essentially from those already met economically by the big boats. Mining engineers, machinery builders, and capitalists in this country are all studying the foreign fields with interest. In many particulars the Russian and Siberian goldfields particularly attract Americans. It is known that the placers are rich and extensive, and the climate is not unlike that already familiar in Alaska and Montana. The people and governments of the two countries have always been on friendly terms, and a number of American engineers are personally familiar with Siberia. Last, but by no means least in importance, British capital is willing to go into Siberia, and it is the Anglo-American enterprises in dredging that are most important. Our excellent contemporary, *Zoloto i Platina*, publishes much that is of interest to dredgemen. We print this week a thoughtful general review of the Russian situation, written by Mr. S. I. Littauer and translated by Mr. W. H. Shockley. The original article is too long to be reprinted in full, and we have omitted an extensive table giving additional statistics as to the 64 dredges now in operation. The November number of *Zoloto i Platina* was exclusively devoted to reviewing the dredging industry in the light of data collected by the Permanent Consulting

Board of Gold and Platinum Producers. A special discussion of the advantage and disadvantage to Russia of inviting foreign capital to participate in the dredging industry is promised later. In this issue it is merely pointed out that Russian dredging has made slow progress as compared with the industry in other countries, that capital has generally been insufficient, and that such boats as have been built and operated have been made possible mainly through long credits from the machinery houses or expensive borrowing from banks. "California dredges", says our contemporary, "would unquestionably make it possible to greatly reduce working costs. For economical, local, and technical reasons, such low costs as are attained in California are impossible in Russia, but they show what a vast area of placers might become workable in Russia by the application of proper methods. The number of dredges working in Russia, about 70, is ridiculously small in comparison with the vast area of auriferous placers that might be worked with their aid. One of the most important circumstances repressing and retarding the development of the dredging industry in Russia, is the lack of the necessary capital. Russian capital is on the one hand too immobile, and on the other too careful to enter into the development of the dredging industry in unknown places; a business that offers, as is shown by American experience, one of the most advantageous opportunities for investment. On this account the initial Russian dredging enterprises must largely rely on foreign capital. The Russian dredging industry can only emerge from its present unenviable condition by the help of the large banks, or by the aid of foreign capital; by their aid it can enter upon a brilliant career, alike profitable to the gold industry and the capital employed. This is the more to be wished since the dredging industry has already trodden the thorny path of experience, inevitably strewn with failures and disappointments. But now the results of dredging, as is shown by technical and economical statistics, are becoming more and more satisfactory." Attention should further be called to the fact that free importation of machinery and mining supplies is still permitted in the Amur and Primorsk districts, and that these are the ones most readily accessible to American ports.

Engineering Ethics

The ethics that should govern engineers in their professional relations, have been much discussed of recent years, and it is a welcome sign of a growing professional spirit. As engineers come to recognize the importance of maintaining the highest standards, membership in the profession will bring more of dignity, honor, and remuneration. If a man thinks of himself as but an artisan or mechanic, he is apt to be treated and paid as one; and to get what he deserves. That engineering stands on a higher plane than this, is due to the pioneers who have placed it there. We, for our part, should guard the future, not by clannish exclusiveness, but by quick and generous recognition of talent, and by a nice observance, each for himself, of the canons of ethics that govern the profession. We are glad to present so clear and admirable a summary as has been compiled by the committee of the Philadelphia Section of the Mining and Metallurgical Society. The San Francisco members of the same Society in discussing the report found much to commend and nothing to criticize. That, in brief, is our own attitude. There are, however, a few points we should like if possible to emphasize.

The duty of respecting scrupulously the limitations of our own knowledge, is not always recognized. Engineering covers a broad field and within it there is room for many specialties. Considering mining engineering only, the three fields, geology, mining, and ore treatment, at once come to mind. A man may be a most excellent geologist and yet be poorly equipped to advise regarding either mining or metallurgy. This is by no means to say that the geologist is not useful. Indeed, the demand for exact geological work never was greater than now, and no large mine examination should be undertaken without the assistance of a competent geologist. Mining, however, requires men of somewhat different temperament and of entirely different training and experience. A man may know little geology and yet sink a shaft or open a stope cheaply and rapidly; but such a man is not necessarily competent to decipher an intricate system of faults or to recognize the limits of a secondarily enriched orebody. The metallurgist, in turn, is a most useful member of the profession, but has his own field; one so broad, indeed, as to include a whole range of specialties. The best of cyanidation experts ought not to attempt to advise a client regarding copper smelting, on the basis at least, of his experience with cyanide. The safe rule is never to attempt anything you are not thoroughly competent to do, and in the other cases to call in a fellow engineer for advice and help. If each one does this there will be fewer mistakes, better-satisfied clients, and more work for everybody. One of the best and most successful mining engineers we know, but one experienced mainly in metal mining, had occasion once to consider a question relating to coal mining. The problems of the colliery are different in important particulars from those of even the largest metal mines, and our friend recognized this. Instead, therefore, of attempting to handle the matter alone, he called in another engineer whose experience had been almost entirely in coal mining. On the basis of the second engineer's report and his own knowledge of his client's needs, he advised them excellently, as the result proved. Such men are at the head of the profession because they know how to utilize the services of others. Under most conditions it is as foolish for a mining engineer to attempt to solve geological problems, as to make his own assays, post his own books, and sharpen his own moils. Failure to recognize this fact limits the usefulness of many a good man and too ready a belief in one's own powers often leads to disaster. It is, as the Philadelphia committee has said, the duty of each engineer to secure assistance or decline any commission which calls him beyond the safe limit of his abilities.

Another matter of much importance is the highly unprofessional conduct of an engineer who accepts presents or commissions from those with whom he transacts business for his clients. We are glad to believe that this practice is dying out. It can not disappear too quickly for the good of the profession. In certain countries and districts it is all too common yet, but the fact that no engineer will publicly defend it, shows how widely it is condemned. As to the vexed question of promotions and contingent fees there is as yet no consensus of opinion, though we believe heartily in the dictum laid down by the committee, that all such matters should be open and above-board. Any arrangement of this sort that must be secret is suspicious, to say the least. The duty of engineers to support professional societies, to cultivate friendly relations with their fellows, and not to dodge responsibility when it comes to them, can not be too often emphasized. To the report of the committee we would add one more dictum, namely, that it is the duty of an engineer to give freely of his knowledge and experience to his fellows in part return for what he enjoys as the result of those who have gone before. A profession that does not recognize the benefits of technical writing and of supporting technical publications, can but degenerate into a secret guild or caste and both these belong to the medieval age rather than to the future.

Development of Western Mining

By J. R. Finlay

*I know little about the University of California; no more than what every educated or semi-educated man knows, that it is a large and flourishing institution of learning which has contributed greatly to the advancement of the arts and sciences in California. Not knowing the student life at Berkeley, I fear I may be bringing coals to Newcastle in some of the remarks I intend to make, which are in protest against forming too hasty a judgment of what is worth while—of what is theoretical and what is practical. I have noticed among the students of some isolated technical schools an impatience, almost a contempt, for knowledge, and hope this atmosphere is not present in any department of the University of California. What I mean by contempt for knowledge is a narrowing down of intellectual interest to some object of plain, or so-called, practical utility. A man may exert himself to become an engineer by learning certain things that he is told are necessary for that purpose. His one idea is to acquire what he calls a profession, but which might just as well be called a trade. He takes no interest in information that he thinks he cannot sell. I have seen graduates of mining schools who had learned how to take solar observations in order to get a north and south line, and yet did not know what the solar system was. I remember one such graduate who was filled with genuine impatience at the idea that it might be worth while to know the difference between the planets and the fixed stars. This is not, to my mind, the attitude of an educated man; it is an attitude of exaggerated and mistaken devotion to the practical.

As a matter of fact, it is hard to tell what is practical and what is not; but I venture an opinion that nothing is more unpractical than a method of thought that narrows the interests of the mind. Anything that adds to the efficiency of the human mind, in the smallest fraction, is putting new worlds at the feet of mankind. What is true of the race is true of the individual. The one function of education is to develop the mind. Any system that tries to teach a trade and not to fertilize the brain is not education. I do not for a moment wish to discredit or discourage the most painstaking application to technical details. In that very direction, perhaps, can intelligence make the most fruitful advances in industrial and scientific pursuits. As an instance, see the great field for economy demonstrated to exist in the scientific study of the commonest kinds of labor. It has been shown that in many cases the output of shovelers can be increased three or four fold by making a scientific study of the size and shape of the shovels to be used for handling different materials. All this is the effect of the awakened mind. It is not the stereotyped action of a man who has no interest in anything not approved by commercial custom; it is not, on the other hand, the accomplishment of one who rashly tries to improve something without understanding it. That certainly is unpractical. It is done by analyzing the facts and discovering that because a thing is taken for granted it is not therefore necessarily understood. It has been found that a laborer might shovel 60 tons a day with no more effort than he had used to shovel 16 tons; although it may be assumed as certain that the laborer prided himself on being expert at his art and felt sanctified and entrenched in centuries of 16-ton shoveling.

Has it ever occurred to you that what we usually regard as physical efforts are really mental efforts? We are seated in a building made of wood, iron, and cement. Is it merely wood, iron, and cement? No; it is a human habitation, a structure of the human organism, an output of the human imagination. Without that last the wood would be a tree, the iron an ore, the cement a stone. Similarly, the mining business is a mental business, not wholly a physical one. We hear people talking of the mineral resources of certain localities as if the mere existence of gold ore would make a gold mine. No! it is men who create gold mines. It is their imagination that creates gold ore; for without the curious psychologic phenomenon that makes men prize gold, it would remain forever unnoticed in the rocks. The development of the mining industry of the future will depend entirely on the development of ideas. Ideas create wants, and industry is the effort to satisfy them. The gold of California had lain scattered through the gravels of the Sierra Nevadas since Tertiary times, but it caused no excitement whatever. Undoubtedly many an Indian had picked up an occasional nugget, but it meant nothing to him. The real significance of the rush to California lies in the rush, not in the gold. The gold might as well have remained scattered in useless yellow fragments in the gravel. The gold was merely the spark that ignited the white man's brain, and the great human rush which followed was the significant event. It was one of the capital acts in the building of an immense empire. It changed the face of nature. It tore down the forests, muddied the streams, started a whole chain of activities in the midst of which we are still living and the end of which we cannot foretell. The controlling factors of the incident were not the existence of gold, but historical events; and the same reasons governed the almost simultaneous exploitation of the Australian goldfields. We must remember that up to the time of the Mexican War, the growth of the United States out of the English colonies had been monotonous, though rapid. The earlier excitements of war and exploration and conflict with the Indians were waning. The main occupation of the people had been to hew out homesteads in the forests. The expenditure of manual labor to do this was frightful. Even after a farm was started, the returns were meagre and slow; the people were poor, and chained to a humdrum pursuit. Nevertheless, they were magnificently prepared for adventure. The youth of the country were all trained in the use of the gun and the ax: they were familiar with the wilderness as well as the farm, and could camp in the woods and cook their own food without any teaching. The Mexican War gave some excitement to the adventurous spirit of these people, and the consequences of the war gave a field for more. A vast stretch of country including California was ceded by Mexico; the West seemed absolutely boundless. The news that California was not only a beautiful, smiling, seacoast country, but that it abounded in gold, was enough to fire the imagination of the plow-wearied youth quite to the exploding point. Nothing could hold them back and the rush that began was unique among the migrations of the white race. It was not only America that was ripe to send her sons to California. Europe had simmered down to a long period of rest after the French Revolution and the wars of Napoleon. The ideas of that time had been repressed, but not extinguished. Steady progress had been made in arts and manufactures, and hopes were secretly growing out of the triumph of democratic ideas. In 1848 revolution broke out in France, Germany, Austria, Hungary, and Italy. In France only were the Republicans successful. In the other countries the old order of things soon triumphed, and hordes of talented, eager, self-sacrificing young men were banished from their homes. What more natural than for these disappointed exiles to turn to a new field where their cherished political ideas were already fully accepted, where there was plenty of room for effort, and where perhaps a fortune might be picked out of the sand? It is true that gold has always had the fascination of romance as well as of value, but it is also true that these circumstances gave to the California goldfields an unparalleled attraction. The effect of this sudden outpouring of the flower of the civilized world upon the development of the West is not, I believe, quite appreciated. It made a great country of California immediately. Before the State was ten years old it was contributing literature that was read over the whole world. From the first it contributed leading men in business and the arts. In mining, the particular industry to which attention was directed, the impress given by the

*Address delivered before the Students' Mining Association, University of California.

'forty-niners' was absolutely controlling. In other countries, from time immemorial, work in the mines was the work of slaves. In our West it was the work not only of free men, but of picked men from many nations. Hard labor underground was gilded by the glamor of romance and enthusiasm. The whole field was at one stroke illuminated by a light of generous enthusiasm which enabled men to create success, and which has not yet wholly died out. We do not hear that any great fortunes came from the early placer mines. A competence, or even a good living, was enough for most of the miners, but as soon as they passed beyond the stream placers and began to work quartz gold mines and the silver ores of Nevada, the business became more complex and needed more thorough organization. It was then that large fortunes began to be made from Western mines. As time went on, capital played a larger and larger part. During the three or four decades following the rush to California, there was a succession of discoveries of new and rich gold and silver districts, in which poor prospectors suddenly became millionaires. The whole mountain country remained a region for stirring adventures, filled with golden dreams and generous impulses. The Comstock lode in the early sixties; Eureka, Nevada, and the Black Hills in the early seventies; Leadville, Aspen, Butte, and the Coeur d'Alene in the early eighties; Cripple Creek and Creede in the early nineties; and finally Tonopah, Goldfield, and the porphyry coppers in the last decade have all contributed their quota of fortunes and excitements. It must be confessed, however, that the golden age of Western discovery has substantially passed. The discovery of new mining camps where poor men may dig out a fortune has not kept pace with the increase of population and the means of travel and transportation. It would be rash to say that no new bonanza discoveries will be made; but it is almost unconceivable that such discoveries will play any great part in the economy of the Western States. For example, there was a great mining craze in Nevada a few years ago, but all the discoveries made in that State in ten years are sufficient to give employment to only three or four thousand men. The whole State gained forty thousand people in the decade while California, without any increase in mining activity, gained nine hundred thousand. Precious-metal mining is losing ground rapidly in relative if not in absolute importance. But other kinds of mining are not losing ground.

All this only illustrates more strongly that the enthusiastic traditional period born of the days of forty-nine has passed. Work in the mines is once more the work of slaves. I speak figuratively. I mean that work in the other man's mine is no longer a stepping-stone to working your own mine which is surely waiting for you in the hills. It is only a stepping-stone to a lease, a farm, or to some other kind of work. Work in the mines is no more hopeful than work on the railroads, and not so healthful. The growth of the Western Federation of Miners is a dumb recognition of this fact. Mining is no longer a cheerful scramble and gamble for gold; it is a stern, dangerous occupation, a dark and disagreeable occupation, in which advancement is slow and competition keen. There is hardly an outlook more gloomy than that of the average prospector on Government lands. The future growth of the mining business will be mainly based on deposits already partly known and on land already owned by private individuals or by corporations. This view of affairs is not by any means so discouraging as it sounds. In part it merely recognizes what has always been true. The fact is, that even in the palmiest days of the West, the percentage of adventurers who actually realized their hopes of fortune was small. In the mining business of today there are many opportunities, perhaps not so many for each person as there were at times in the past, but much more varied. The mining business which has grown out of the days of forty-nine is really a business. It has lost its romantic side. A favorite phrase for some people is the 'mining game.' You might as well talk about the 'farming game.' Let no young man go into the mining business expecting to find the conditions described by Bret Harte and Mark Twain. That belongs to the past; a very recent past, to be sure, but just as truly of the past as are the deeds of Achilles and Odysseus.

San Francisco has decided to hold in 1915 a great industrial exposition to celebrate the completion of the Panama Canal, which the Government engineers promise will be opened year after next. This is the crowning chapter in the long book of the opening up the North American Continent by a complete system of transportation. Forty years ago, one transcontinental railroad had just been completed which allowed travel from San Francisco to New York. Now we have in the United States alone, seven or eight through railroads, every one of which takes passengers from coast to coast in four days. Canada will shortly have three such systems, and Mexico two or three. It is not too much to say that the whole Pacific area is as well provided with transportation today as the region east of the Mississippi was thirty years ago. The country is no longer a wilderness, but is like the rest of the civilized world in all essential respects. This means that business and industry are on practically the same footing as in the rest of the world. The year that saw the Panama Canal definitely undertaken saw also, on the other side of the Pacific, a still more significant event—the Russo-Japanese war. That was a swing of the pendulum of history which marked a great epoch in the progress of mankind. Ten years ago the resistance of any Asiatic nation to any leading European power looked like a fantastic dream. In 1905 the victory of Japan over Russia settled probably for hundreds of years some very important questions. It showed some limits to the dominance of the white race, stopped the disintegration of China, and caused the world to do a vast amount of thinking. That war was as important to the United States as to other nations. It brought home to us the truth that we could not expand farther in Asia; it made our continued possession of the Philippines seem doubtful; it showed us that our future development must be in the territory already occupied. The agitation against the Japanese in California a few years ago was a compliment to that people, for the underlying motive of the agitation was not contempt, but fear, and aversion based on fear.

There are many features of our present-day progress that are affecting industry profoundly, but I will confine myself to just one more, the general acceptance of the corporation as a means of doing business. The reason is that the corporation is economical. It accomplishes results with a less expenditure of capital and labor than individuals can. Corporations are accused of growing larger and larger, of absorbing more and more of the resources of the country. That is true, but who owns the corporations? The United States Steel Corporation has, I believe, 65,000 to 70,000 stockholders. Even Goldfield Consolidated has 7000. The fact is that corporations are performing two apparently opposite functions. They are removing property from the control of the individual and at the same time making it easier for the individual to get property. Few men ever were rich enough or fortunate enough to own a mine as an entirety. Very few are so poor that they cannot own a share in one. There is a significance in this. The mining business of the future will be more and more a business of corporate investments. The mining engineer of the future, or of the present for that matter, must know the value of mining stocks if he wants to make money. He must invest his money in mining stocks. It is just as much his business to do so as it was the business of the son of the pioneer farmer to acquire a farm. If the mining business is not good enough for you to invest in, it is not good enough for you to work in. Every man of consequence should own some property. You are certainly better qualified to own property in a business that you understand than in some business that you do not understand. It has been so much a practice to sell worthless wild-cat stocks to a gullible public that to many people mining stock is a joke. The real growth of corporate mining will end this. A strong move-

ment is under way to cause mining companies, as well as other corporations, to publish such reports on their property and operations as will allow any competent man to have a fair idea of what their property is worth. The outcome of this movement is inevitable; the reports will surely be better than they used to be. Furthermore, men in charge of corporations are put there mainly because their associates can trust them. There are few men who will be honest in private and liars in public; if a man is honest to his associates he will be honest to the public, and if he makes a public report it will be an honest report.

Let me point out one or two directions where mining, or at least its cognate industries, is likely to make great expansion. It seems to me that the manufacture of cement and fertilizers will greatly increase. The last few years have seen an enhancement in the value of agricultural land. This has come to stay. The rise has been due to the rising price of farm products and to the realization that the supply of new land no longer exists. All of the Pacific States gained in population from 60 to 100% in the last decade. California is nearly as large as France; San Francisco will one day be as big as Paris. The State can hold easily fifteen or twenty million people. The wealth of the country is mainly in its soil, and its soil must be made productive by irrigation and kept productive by fertilizing. If we realize that there are in California twenty million acres of arable land which has undergone an enhancement of fifty dollars an acre, we have an additional property valuation of a thousand million dollars. That is worth maintaining, though it may easily mean the use of fifty million dollars a year in fertilizers. At the same time, the regulation of streams by means of reservoirs for the purpose of securing water for irrigation and for power, and the building of millions of houses and thousands of miles of roads, will require a prodigious amount of cement. I believe that there will be required somewhat more cement per capita on the Pacific Coast than in the East. If San Francisco is to be as large as Paris, it must be built so that it will be secure from earthquake and fire. Time and the increasing cost of timber will see it built of concrete and steel. You may say that the manufacture of fertilizers and cement is not mining. If you say that, it is because you are thinking of the traditional underground precious-metal mine. Copper and iron ore are being mined by steam-shovels. Cement rock and phosphate rock belong to the crust of the earth just as much as does gold quartz. You might as well work in a cement mill as in a copper smelter; as well in a fertilizer plant as in a quartz mill. Your technical education equips you as well for one as for the other. All mining is in a sense manufacturing; productive mining certainly is. Unproductive mining, merely looking for something, is different. Unfortunately, that is what many people understand by mining. They think it means merely looking for something until you find it, as if a fortune could be picked up as easily as a quarter of a dollar, when once you run across it.

Gold will be sought in the future as in the past, in the wild places of the earth. Canada, Siberia, the middle part of Africa, South America—these are the countries where new discoveries are being made, or rather, in some cases, old discoveries are being re-made. The gold output of Europe is insignificant; that of the United States and Australia either on the decline or soon to decline. This means that gold supplies do not last many generations in the regions most desirable for human habitation. The problem before the rising generation is not to find new resources, but to utilize wisely the old ones, or at least the known ones. It is the very time for the educated man with the alert mind. Reorganization is the order of the day. It may be reorganized along any one of many lines. It may be political, financial, technical, or industrial. Mining is one of the great businesses of the country and of modern civilization. It is certainly undergoing a rapid financial reorganization. They say we are becoming a nation of employees. So we are—let us recognize that fact. But we are also becoming a nation of employers, for we are becoming a nation of stockholders.

Sand Filling

By R. W. Schumacher

*The plan of commencing sand-filling in several of the subsidiary mines was mentioned at the last annual meeting, and, during the year under review, further proof has accumulated that a comprehensive system of filling worked-out areas is desirable. Sometimes other methods of supporting the ground, such as reef pillars and waste packs, are useful in holding up thin layers of hanging wall a few feet thick, but they fail entirely when enormous pressure takes place from the overlying strata, as in the neighborhood of the Ferreira Deep, where a large area of ground is gradually settling. Experience has shown that reef pillars under these circumstances usually punch into the hanging wall or crumble away, thus diminishing their support and allowing the ground to fall in. Waste packs, again, crush to about half their original width, and often collapse altogether. A sand pack flushed in by water will also have to give way to some extent under such heavy pressures, but, as far as is yet known, the compression will not amount to over 5 or 10% of its thickness, and then the sand will be left in a condition of solidity almost approaching the natural formation of the rock. One of the main differences between sand-filling and other methods of supporting the hanging wall lies in the size of the packs used. Pillars or waste packs may measure 40 by 40 ft. square, but, owing to their heavy cost, they would almost necessarily be scattered and at considerable distances from one another. A sand pack, on the other hand, has practically no limit as to dimensions, and will, as mentioned, after a slight compression, solidify every part of a worked-out area. On the Ferreira Deep a sand pack has recently been completed measuring 700 by 300 ft., and even larger packs will soon be started, the idea being to fill the entire space between incline shafts in the upper workings. Since June 1910, when filling started at this mine, 130,000 tons of sand have been deposited, and recently the plant has been duplicated, so that the process of filling can be further accelerated.

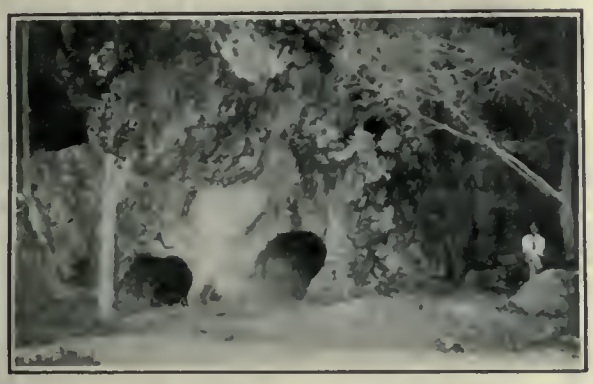
At the Crown Mines three plants are being constructed to fill certain exhausted areas. Actual filling commenced in the middle of November 1910, and it is expected that in a few months the company will be able to flush into the mine between 50,000 and 60,000 tons of sand per month. At the Geldenhuis Deep, where sand filling is now just commencing, there are two objects in view; the first is to lend support to two of the vertical shafts, and the other is to assist in the recovery of a large number of pillars under the railway line, which can be extracted only on the condition laid down by the Government that a considerable area be packed with sand. At the Rose Deep, where preparations for sand-filling are nearing completion, the conditions are again different. The plan at this mine is to secure cleaner and cheaper mining in the main reef leader and bastard reef which overlie exhausted main-reef workings in close proximity to them. The waste parting is sufficiently large to have rendered it uneconomical to mine the upper reefs together with the main reef in one stope, and is sufficiently narrow to make it difficult to support in the ordinary way when mining the reefs separately. It will be gathered that at most of the mines operated by this company this method of sand-filling is in vogue. Other mines, as it becomes necessary, will probably also adopt the same practice, and it would appear likely that, in the future, sand-filling will in many cases gradually form a portion of regular mining operations, partly in order to afford more safety to the underground workers, and partly also to enable cleaner mining to be done; the expensive work of cutting pillars will thus be avoided and the extraction of the entire reef in the locality stoped will be rendered possible.

*Abstracted from report of the annual meeting of the Rand Mines, Ltd., published in *The South African Mining Journal*, March 25.

Mina Grande, Sonora, Mexico

By T. B. Sweeny

One of the most interesting of the famous *antigua* mines of Mexico is the Mina Grande, in the Baroyeca mountains, District of Alamos, State of Sonora, about thirty miles easterly from the town of Esperanza, on the Southern Pacific Railroad of Mexico. The known history of the mine dates back to the year 1792, when the first bonanza, afterward known as the Dolores, was discovered by Padre Don Francisco Joaquin Valdez, curate of Baroyeca. Various lodes in the immediate vicinity, however, had been worked for generations previously, and Baroyeca was already a town of considerable importance. After the discovery of the Dolores bonanza the great wealth produced thereby made Baroyeca famous through Mexico and Spain, and the place eventually became the capital of the District of Sonora, which at that time included, in addition to the present State of Sonora, all of the State of Sinaloa and a large part of California and Arizona. The town at this time is estimated to have had a population of from eight to ten thousand people, all of them dependent for their support, directly or indirectly, upon the mines. The extent of the industry is plainly evidenced even now by the ruins of the *rasos*, or small native smelters, scores of which are



Old Dolores Adits.

scattered over the site of the old town. It is conservatively estimated that the mine must have produced at least ten million pesos of silver since 1792, and this notwithstanding that none of the old workings go to any considerable depth.

The famous cathedral of Baroyeca, erected by Padre Valdez shortly after his discovery of the Dolores bonanza, was for many years considered one of the finest church buildings in Mexico. The walls of the sanctuary and the altar were literally covered with massive silver plates, and it is stated that the value of the church vessels alone was over two hundred thousand pesos. The belfry with its chime of bells and parts of walls five feet thick are still standing, although the building has been set afire half a dozen times, and everything of value long since carried off by bands of Indians or by the revolutionists who have time and again raided that part of the State of Sonora. In addition to building this cathedral and endowing it liberally, Padre Valdez provided generously for all his relatives and intimate friends, leaving at his death a fortune which must have amounted to several millions of pesos. After his death the mine was worked for many years by his relatives, who finally disposed of it to Don Jose Maria Almada of Alamos, who some years later died, having meantime accumulated a fortune estimated at half a million pesos. In 1840 the property was taken over by Don Salvador Esquer of Baroyeca and his two brothers, who for various reasons were unable to operate the mine to advantage or continuously, but who nevertheless retired in fifteen or sixteen years with a capital of about two hundred thousand pesos each, selling out to Don Jose Maria Lopez. The latter worked the mine more or less constantly until about 1880 and met with considerable success, although handicapped by lack of ventilation at depth, which prevented him from following up the richer lodes.

Between 1880 and 1900 the mine was worked with fair success at different times by several small companies, none of which, apparently, were possessed of sufficient capital to work the property to the best advantage, and they all collapsed sooner or later through this cause or on account of bad management, inability to get proper machinery into the mine over the almost impassable trails, or other difficulties. Their work was often interrupted by Yaqui Indian raids, which made mining in Sonora a particularly hazardous occupation during that period. Finally in 1900 the property was taken over by Don Alejandro Esquer, grandson of Don Salvador, and two or three associates, and they, although handicapped as all the others had been by lack of capital, obtained good results during the short time they owned the property. Don Alejandro had somewhat better luck than his associates and was very loath to sell, but when finally compelled to do so through the pressure brought to bear on him by his partners, stipulated that he should have the privilege of working freely in Tiro de Dolores from then until the date when actual delivery of the property to the new owners should take place. In the twelve days which elapsed, working with only fourteen men and in the crudest possible fashion, he managed to extract over seven thousand pesos' worth of metal. He had also previously found in the old workings several small pillars of rich ore.

Native Vaso in Operation.

Samples which he recently gave to Boston men assayed as high as 4000 oz. silver per ton.

Senor Pareda, one of the few survivors of the last years of *antigua* mining in Mexico, now a very old man, and who was manager of the Mina Grande in his younger days, states that the rich bonanzas frequently yielded ore running anywhere from 500 to 7500 oz. silver per ton, and that at the bottom of one of the winzes in El Tajo tunnel streaks of sulphide were found running as high as 50% silver; so rich as to be almost malleable. In those days he affirms that the old bonanza workings were often filled with what was regarded as second-grade ore of no value, although it ran as high as 50 oz. per ton, and that quantities of this ore are there still. With modern methods, ore one-half as valuable could be worked to good advantage. Since the time of Senor Don Alejandro little work has been done on the property until within the past year or two. Recently, however, Boston and New York men have done more or less exploratory work, with very encouraging results. Small veins of ore running as high as $80 per ton in silver and lead were found in the new Tempisqui tunnel, which was driven within fifteen or twenty feet of the abandoned Dolores tunnel, and these veins had been followed for about one hundred feet, up to the time when the disturbed political conditions in Mexico made it seem advisable to discontinue mining operations for the present. Enough work was done, however, to warrant the belief that with adequate capital and proper machinery this wonderful old mine could be made to duplicate, if not to greatly exceed, the success which has attended the efforts of British and American capital to develop many other Mexican *antiguas* along modern lines.

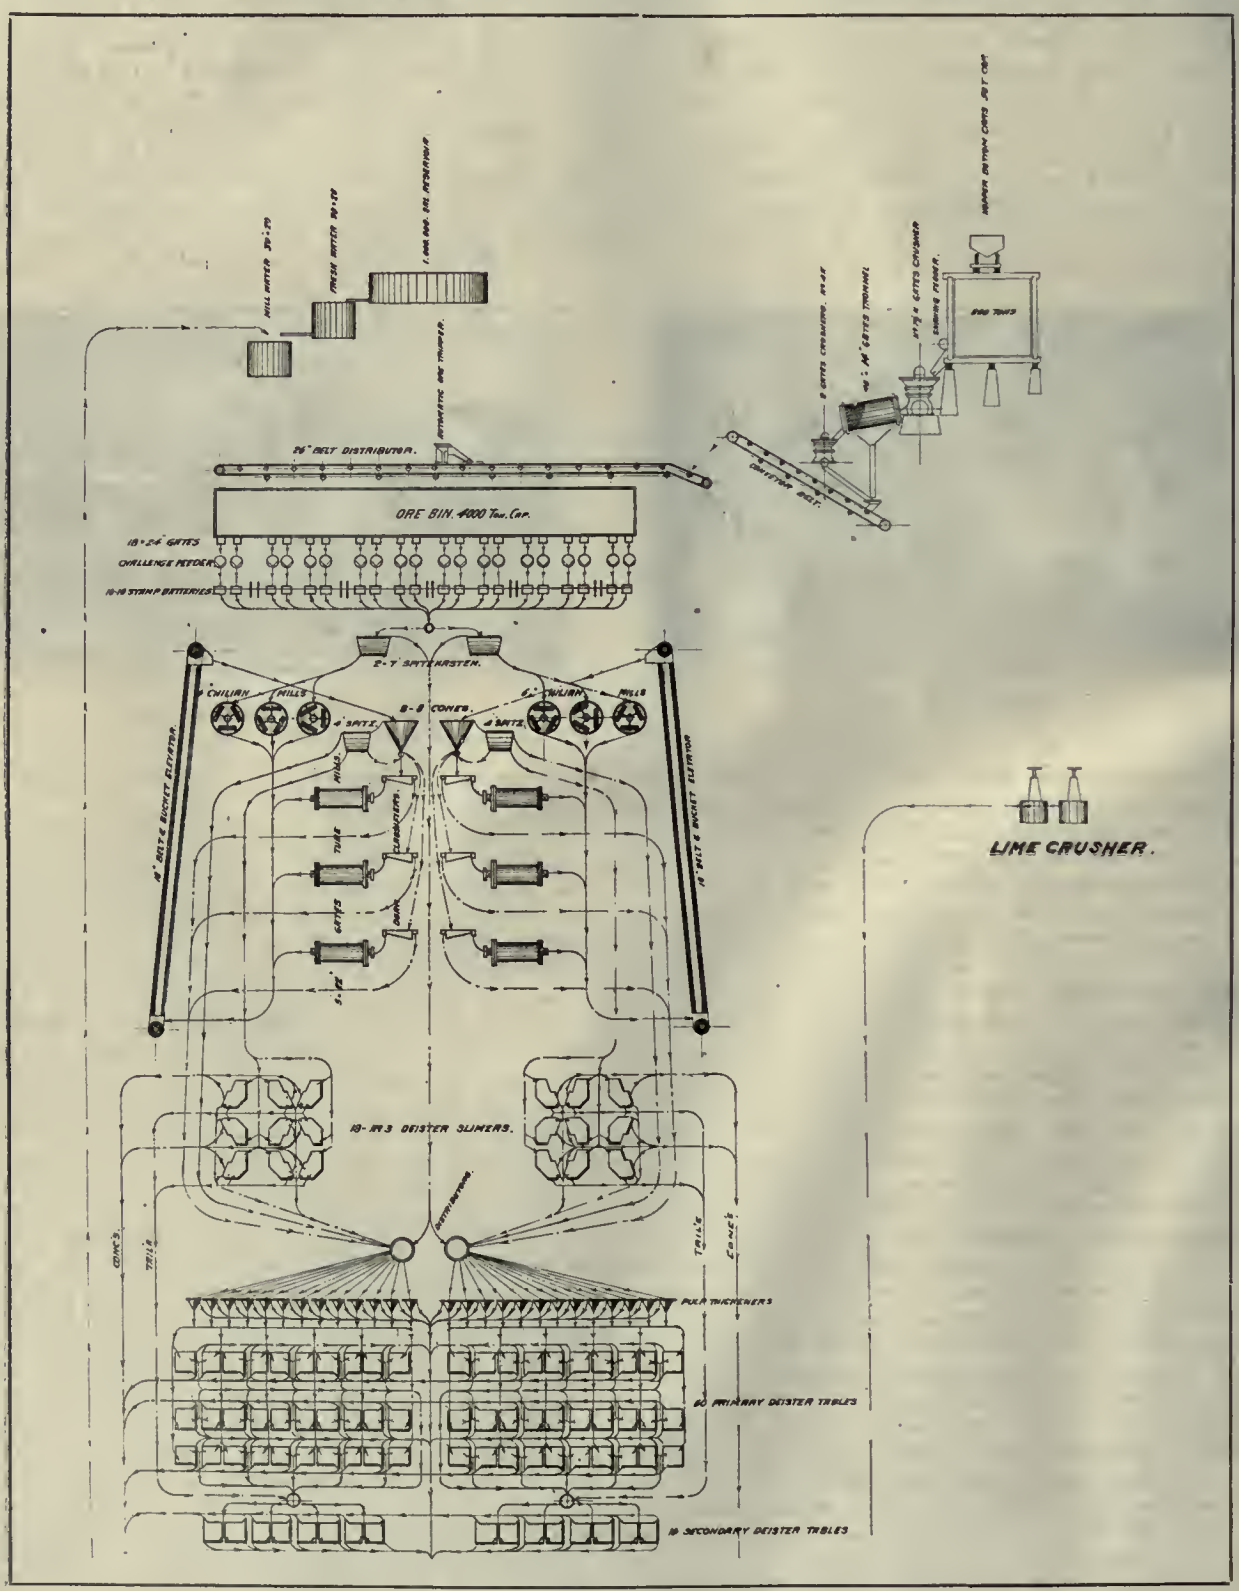
Operation of the Goldfield Consolidated Mill

By J. W. Hutchinson

(Continued from page 652.)

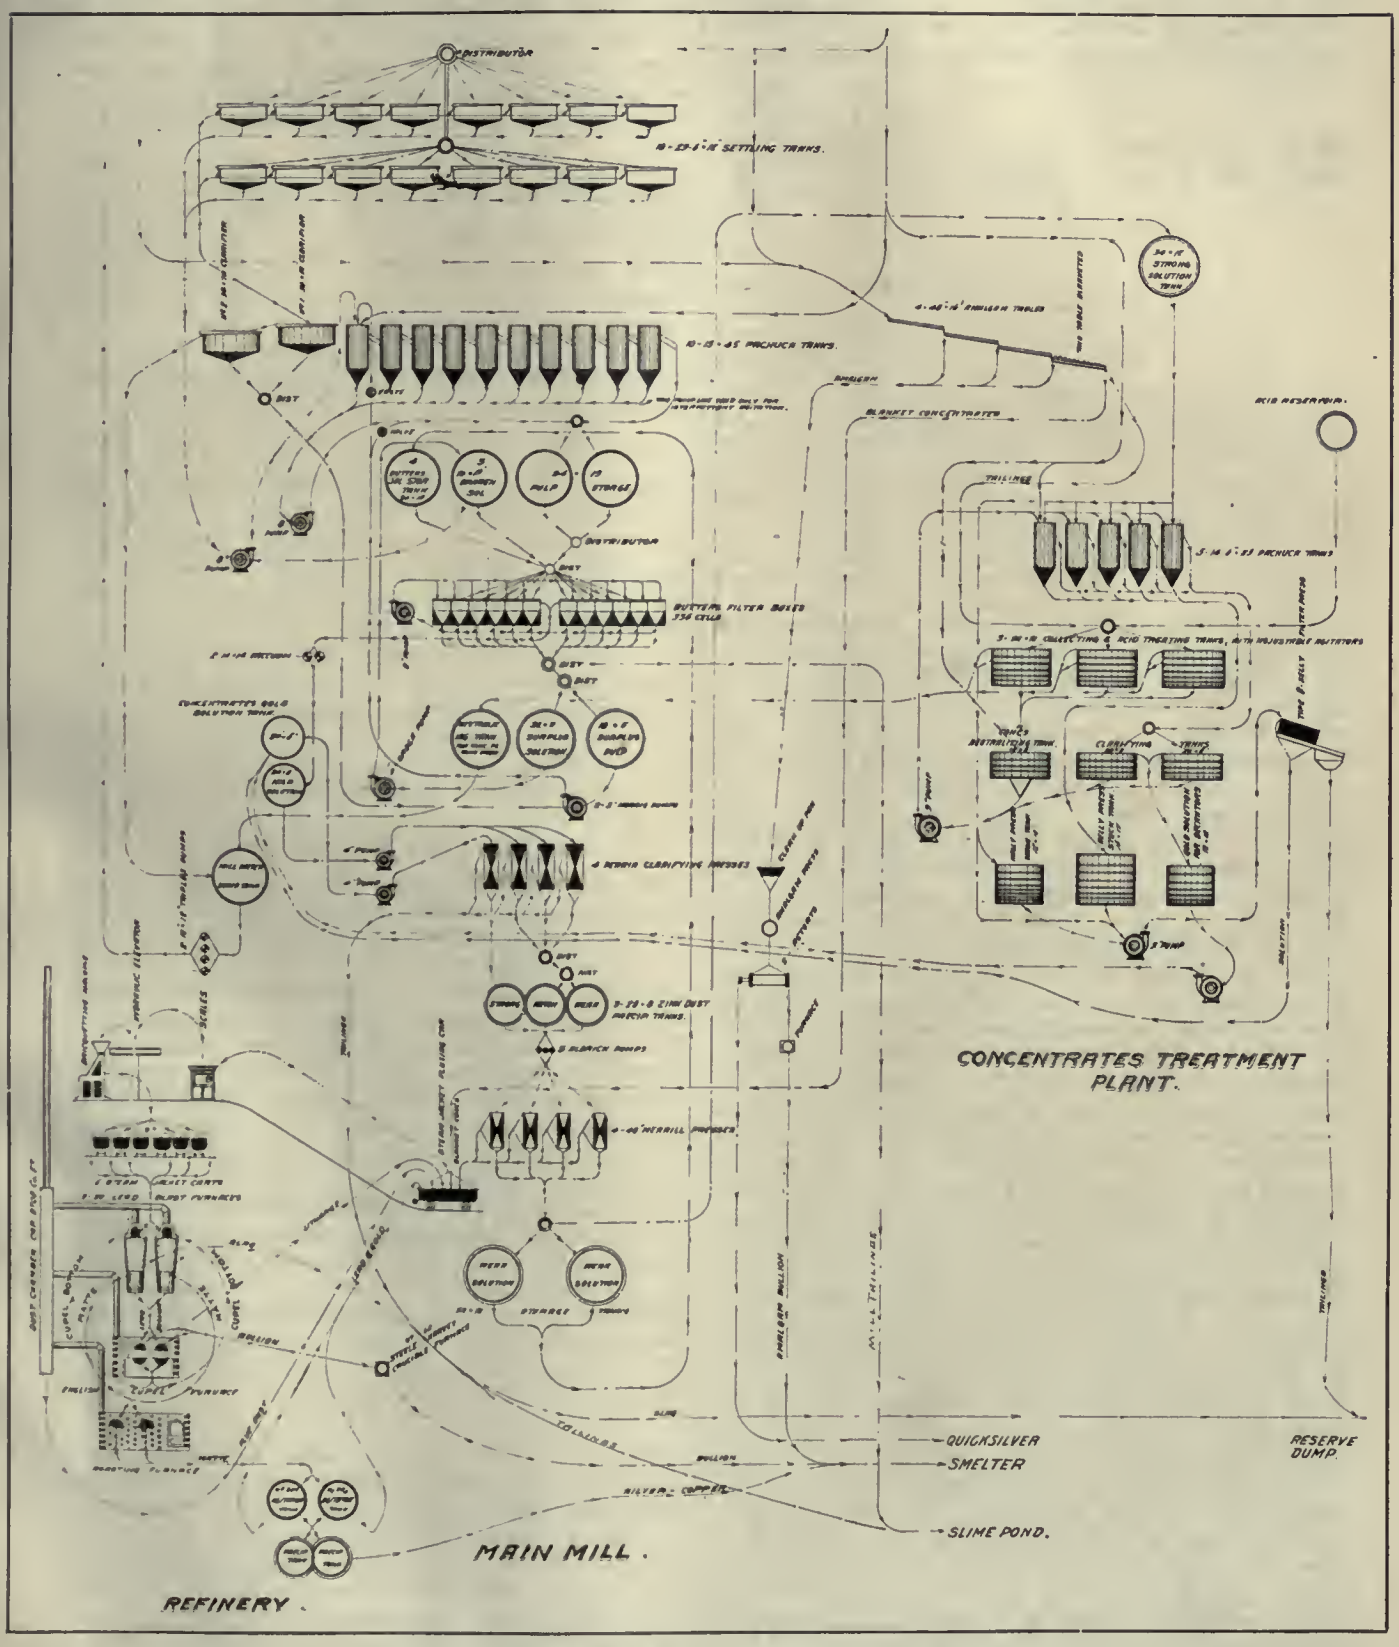
FILTERING

From tank No. 10 of the agitator series the pulp gravitates to two 34 by 12-ft. pulp-storage tanks fitted with mechanical stirrers. These tanks are situated about five feet above the top of the filter-boxes. On the same level are two wash-solution tanks which will be called 'No. 3 and No. 4 above' in the following description. Reference to the flow-sheet will assist in following the cycle of operations. From the pulp-storage tanks through a 16-in. pipe-line the pulp gravitates to two steel filter-boxes with 6 hoppers each. The boxes contain 168 leaves each and are worked as one unit. All valves on the 16-in. filling and emptying line, are actuated hydraulically with levers from a central switchboard. After the cake has been formed the excess pulp gravitates through a 16-in. line to an excess-pulp tank from which it is elevated to the two filling tanks by means of 5-in. Morris pumps. Wash solution is run in from 'No. 4 above', which tank is filled with precipitated solution direct from the barren sump-tanks. After washing and dropping the cake, the supernatant solution is decanted to the excess-solution tank, from which it is elevated to 'No. 3 above' by means of 4-in. Krogh pumps. The solution for diluting the charges from the dewatering



Flow-Sheet of Goldfield Mill *(Continued on Opposite Page).*

tanks is drawn from 'No. 3 above' and discharged into No. 1 Pachuca of the continuous system. In this way, by using the solution which has been in contact with the filter-cake once, for agitating the new charges, the accumulation of gold in wash solution, which is the main 'talking point' of the opponents of submerged vacuum-filtration, is avoided. The value in wash solution here is directly dependent on the efficiency of the precipitation, and while absolute recovery of dissolved metal is not claimed, the loss is unavoidable. Furthermore, it has been demonstrated beyond a doubt that additional extraction is caused by the leaching action of the wash solution through the cake, which cannot be accomplished by means of agitation unless the tailing from the agitator is treated with a freshly precipitated solution. The amount of gold dissolved on the filter may be *reduced* by longer agitation, but the point has never been reached where the wash solutions do not dissolve gold in appreciable quantities. Ordinarily, this amounts to 30c. per ton. During June of 1910, when the plant was running at 70% capacity on account of the loss of 30 stamps by fire, the pulp was agitated for six hours longer than had been customary with full tonnage. The tailing from the Pachucas assayed lower, but the filters still gave additional extraction, though to a less degree than was normally the case, indicating that all the gold dissolved by longer agitation would have been recovered on the filter. The following comparison, taken from the June records, is interesting:



FLOW-SHEET OF GOLDFIELD MILL *(Continued from Opposite Page).*

	Oz. Au.
Tailing samples of 91 charges from Pachucas to filters (thoroughly washed with water)	0.095
Samples of 200 Butters filter discharges from same pulp	0.088
Extraction on filter	0.007

It is also believed here that the completeness of the displacement of dissolved gold in the cake, as well as the additional dissolution of gold on the filter, is not as dependent on the quantity of wash solution passed as on the length of contact. Consequently, I prefer to wash for a longer period with reduced vacuum. The time allowed for this operation ranges from 85 to 100 minutes. During this time 1⅛ tons of wash solution per ton of ore is passed through the cake, of which solution the following are typical assays, the moisture in discharged pulp being 33⅓%:

	No. 1. Oz. Au.	No. 2. Oz. Au.
Effluent solution making cake	0.192	0.20
Effluent wash at end of 10 min	0.17	0.19
" " 20 "	0.166	0.185
" " 30 "	0.164	0.182
" " 40 "	0.158	0.168
" " 50 "	0.08	0.092
" " 60 "	0.04	0.03
" " 70 "	0.03	0.025
" " 80 "	0.025	0.022
" " 90 "	0.015	0.015
" " 100 "	0.006	0.015
Sample solution in hoppers 10 min	0.001	0.008
" " 20 "	0.001	0.008
" " 40 "	0.001	0.007
" " 60 "	0.002	0.007
" " 80 "	0.002	0.010
" " 100 "	0.002	0.010

Assuming that the amount of solution discharged during the 10-minute intervals is constant, which is perfectly fair, the average value from the assays of the effluent wash for test No. 1 is 0.085 oz. gold, and for test No. 2, 0.092 oz. gold. Naturally this average value is not correct, since the solution is sampled intermittently during a process of gradual reduction in grade, but for the purpose in view it is sufficiently close. It will be noticed from the tables that only between the 40, 50, and 60-minute samples is there a decided drop in value. At the end of the fiftieth minute, in both cases given and in numerous tests made, 87% of the total value of the effluent wash has been picked up. The last fifty minutes and 50% of the total solution passed, are required to accumulate 13% of the total value. In both cases, based on the original assumption that the flow is constant for each 10-minute interval, only 1c. per ton of ore is removed from the pulp during the last ten minutes of washing. In test No. 1, assuming that the total moisture of 33⅓% is of the same value as the one-hundredth minute sample, which, on the face of it, is unfair to the filter, the unwashed gold left in the pulp amounts to 0.003 oz., or 6c. per ton. In test No. 2, in which the wash solution is high, due to the higher value in the barren sumps, the unwashed value is 0.0075 oz. gold, or 15c. per ton. By referring to the subject of precipitation, it will be noticed that during the whole time of operation the barren sump solutions have averaged 0.004 oz. gold; from which fact it is safe to state that the soluble gold left in the discharge pulp has not exceeded 6c. per ton, discharged. When the filter is credited with the additional extraction obtained on it, which cannot be obtained with those filters passing large volumes of wash solution in a short period of time, the adoption of the submerged vacuum-filter has certainly been justified on this ore. The filter plant contains 33,600 sq. ft. of filter surface and averages 50 lb. of slime filtered and 120 lb. of solution recovered per square foot of filter per day. The usual Butters automatic acid-washing apparatus is used to circulate a ½% solution of HCl through the leaves to remove the carbonate of lime. Ten leaves are acid-treated each day, which makes a complete cycle in 34 days. It is worthy of special mention that the original filter-cloths are still intact after 27 months operation, and that they will undoubtedly wear 12 months longer. The tailing is discharged through twelve 12 by 12-in. flat Wheeler gate valves at the bottom of the hoppers into a tunnel, through which it gravitates to the slime pond. For the information of a certain distinguished gentleman who writes an annual review of cyanidation, and for the attention of his readers who may be misinformed, I beg to state that never, since the beginning of operation, has wash-water been added to the tailing discharged from this plant to be settled and returned to the mill for subsequent precipitation, and that the percentage of moisture in the discharged pulp does not now exceed and never has exceeded 35%. Any excess solution built up from the incoming moisture from the de-waterers is carefully precipitated, stored until the assay-value has been determined, and wasted only when the value does not warrant further expense. The following data is representative of normal operations:

Filter Cycle.	Min.		Min.
Filling boxes with pulp	10	to	10
Making cake	60	"	80
Emptying excess pulp	14	"	14
Filling with wash solution	10	"	10
Washing	85	"	100
Decanting and discharging	20	"	20
Total time per cycle	3 hr. 15 m.	to	3 hr. 50 m.
Tons per cycle	125	to	150

COST OF FILTERING, INCLUDING UP-KEEP OF SLIME-POND

Year	1911	1910	1909
Tons	850	850	600
	Cents.	Cents.	Cents.
Labor	3.6	4.1	4.3
Supplies	1.2	1.7	1.9
Power	2.2	2.6	3.1
Total	7.0	8.4	9.1

(To be continued.)

April Copper Review

By Misha E. Appelbaum

The copper market during the greater part of April was in a stagnant condition; most sales were made at 12¼c., delivered thirty days, for both Lake and electrolytic. The domestic consumption showed a sharp shrinkage, but the export shipments were on a fairly large scale, and this with 12,000,000 lb. smaller production than the month before, resulted in an increase in the visible supply of only 3,500,000 lb.; however, the net result for the month was a decrease, since the shrinkage in the European visible supply was greater than the increase in the domestic surplus. May 11 the market is weak, and sales have already been recorded as low as 12⅛c., delivered thirty days. I can only repeat, that unless there is a sharp improvement in business, or a radical curtailment in the production takes place, lower prices will be made. It becomes more and more evident that the real curtailment will come if the price of metal should fall to 11c. A lot of smelters which do custom business with small mines, will then have a smaller production, and it is hoped, for the good of the trade, that this decline will take place as quickly as possible.

Missouri has become the State which produces the largest quantity of lead, having passed Idaho in 1907. In 1909 it produced 40.46% of the total, compared with 27.57% furnished by Idaho, 18.30% by Utah, 8.32% by Colorado, and 1.33% by Nevada, the other States contributing less than 1% each. Missouri produces over 94% of the supply of soft lead in the United States. In 1910 Missouri produced 161,659 tons out of a total of 372,227, according to the U. S. Geological Survey.

The Dredging Industry in Russia

By S. I. Littauer

(Translated by W. H. Shockley.)

*As early as 1906 the Permanent Consulting Board of Gold and Platinum Producers began collecting details as to the working of Russian dredges. In No. 17, 1910, of *Zoloto i Platina*,† was published the fourth of a series of tables (for 1909) showing the production of Russian dredges, and in the present number is published a combined table for the operations of the last four years. This table gives sufficient data to critically appraise the industry in general, and to point out the future importance of the business in Russia.

As the following statistics show, the dredging industry plays an unimportant part in Russian gold and platinum mining.

	1906. Troy oz.	1907. Troy oz.	1908. Troy oz.	1909. Troy oz.
Gold and platinum.				
Total quantity produced in Russia	1,377,019	1,392,239	1,518,002	1,730,555
Total amount produced by dredges	43,027	53,138	70,307	77,417
Percentages	3.1	3.8	4.6	4.5
Gold.				
Total quantity produced in Russia	1,191,271	1,218,657	1,360,851	1,566,242
Total quantity produced by dredges	36,602	47,977	59,643	58,352
Percentages	3.0	3.9	4.4	3.7
Platinum.				
Total quantity produced in Russia	185,748	173,582	157,151	161,313
Total quantity produced by dredges	6,425	5,161	10,664	19,065
Percentages	3.5	2.98	6.8	11.6

The production of some districts for 1909 is obtained by doubling the official figures for the first six months of 1909.

It is seen from the table opposite that Yenisei—where nearly all the gold accessible to hand-labor has been worked out—would be dead were it not for the development of dredging. The number of dredges built and working on Russian gold and platinum mines is shown by the following:

Year.	Existing.	Working.
1906	32	32
1907	54	51
1908	57	51
1909	64	50

The number of dredges has doubled during the last three years, the greater number having been constructed in 1907. It is very characteristic that of the 64 dredges already constructed only 50, or 78%, were working in 1909. The reason for this abnormal phenomenon is that in 1905-1906, when many dredges were built, they were placed on the claims without proper preliminary prospecting. The results obtained from the working of these dredges were so poor that a number of the claims have stopped working and the dredges are now idle. Besides, the construction of many of the dredges proved to be unsuitable for the gold deposits they were to work, and the dredges are now idle during the period of reconstruction.

According to the size of the buckets, the existing dredges are classified:

Dredges.	Cubic feet.
1	1¼
1	2
2	3
1	3½
2	4
16	4½
13	5
2	5½
1	6

Zoloto i Platina, Nov. 1, 1910.

†See *Mining and Scientific Press*, Dec. 10, 1910, for a translation of this article.

There is no information relating to the three remaining dredges. On the mines of the Moscow Forest Co., Putiloff Works, Imperial Cabinet, and the Brothers Yacoleff, have been placed dredges of the American type, with close-connected buckets. These dredges with 3 to 3½-cu. ft. buckets compare in productiveness with a 5-ft. bucket, and the 5 to 5½-cu. ft. buckets compare with a 7-ft. bucket dredge of the ordinary New Zealand type.

Although the absolute amount of the precious metals extracted by dredges increased in four years by 34,390 oz., or 80%, yet the increase compared with the total gold and platinum production was but 1.4%; this is because of the rapid growth of the gold production, which amounted to 374,971 oz., or 31%. If it be remembered that this increase in the production of gold has been due in great part to the output of the Lena district, and other regions where there is no gold dredging, then the rôle of gold dredging in the industry appears more important. Indeed, in some districts dredging assumes a predominant rôle, as is seen by the data in the annexed table. The product of the Lena district for 1906 was 301,768 oz.; for 1907, 315,263; 1908, 364,478; 1909, 432,178.

	Troy oz. 1906.	Troy oz. 1908.	Troy oz. 1909.	Troy oz. 1907.
Northern Verkhoturia district:				
Total gold and platinum	34,838	29,834	33,010	17,142

Dredge gold and platinum	.....	.....	.....	1,359
Percentages	.....	.....	.....	4.61

In Russia dredges of small capacity, with buckets of 4½ to 5 cu. ft., predominate. Among the recent dredges those with 7-ft. buckets are the rule; this is justified; for, with the short summer season and relatively low-grade gravels, the profit of working such dredges is greater. The difference in cost of maintaining a 4½ and a 7-ft. dredge is relatively small, while the difference in productiveness is about 50%. The existing dredges are found in the following gold districts: Northern Verkhoturia, 7; Southern Verkhoturia, 6; Northern Ekaterinburg, 9; Western Ekaterinburg, 1; Southern Ekaterinburg, 1; Verkneuralsk, 1; Altai, 1; Yenisei, 34; Bureinsk, 2; Primorsk, 2; total, 64.

Technically speaking, the dredges do not work satisfactorily. A well constructed dredge, properly repaired during the winter, ought to give a working day of not less than 18 hr., allowing 6 hr. daily for running repairs, and for the clean-up. A working day of this length is reached by the American dredges. On studying the tables, it is seen

that such an average is only attained by the following dredges:

	Hours.
Maria, Neviansk Works	22.6
Savvinix A. A.	20.4
Verx-Isetskix Works	19.6
No. 1, Moscow Forest Co.	19.3
Mechta, Borovinsk Co.	19.2
Spassky Co.	19.1
No. 2, Moscow Forest Co.	18.9
No. 3, 'Draga' Co.	18.2
No. 2, 'Draga' Co.	18.2
No. 1, Nijni Tagil Works.	18.0

Hence, of 64 dredges, only 10, or 15.6%, work normally. Bearing in mind that the unsuccessful working of the first years ought to be ascribed to the inexperience of the administration, and of the dredge managers, and that by 1909 many of these defects had been overcome, the working in 1909 should show better results. This is the case, and the following table shows an average working day of 18 hr. for the following dredges:

	Hours.
Savvinix A. A.	21.0
No. 2, Moscow Forest Co.	20.1
Spassky Co.	20.0
No. 2, Spassky Co.	19.4
Maria, Neviansk Works.	19.2
No. 1, Moscow Forest Co.	19.2
Mechta, Borovinsk Co.	19.0
Verx-Isetskix Works	18.8
No. 1, Nijni Tagil Works.	18.8
Fedorov G. M. Co.	18.7
Neviansk, Neviansk Works	18.6
No. 3, 'Draga' Co.	18.5
No. 2, Heirs of Count P. P. Shuvalov.	18.3
No. 2, Heirs of Count P. P. Shuvalov.	18.3
Zauralsk Mining Co.	18.2
Alexandrov Co.	18.0

This shows that in 1909 the number of satisfactorily working dredges had doubled, and was 16, or 25% of the existing dredges, or 32% of the dredges working.

The ideal work of a dredge may be calculated on the assumption that a rate of ten buckets per minute is kept up, and that each bucket is two-thirds full. Under these conditions the hourly product should be:

Bucket capacity, cubic feet.	Cubic feet per hour.
2	800
4	1,600
4½	1,800
5	2,000
6	2,400
7	2,800

Such an average, or a greater production, is shown only by the following dredges: Maria, Neviansk Works; A. Ermolov, Neviansk Works; No. 2, Neviansk Works; No. 4, Draga Co.; No. 6, Draga Company.

The following dredges show 75% of the theoretically possible production: Sosvinsk Co.: No. 1 and 2, Heirs of Count P. P. Shuvalov; Bogoslovsk Mg. Co.; P. Yacolev, Neviansk Works; D. Konovalov Works; Neviansk Works; P. Boklevsky Works; Von Cruz Works; Spassky Co.; No. 2 and 3, Fedorov G. M. Co.; No. 1, 2, 3, 4, and 5, Draga Co.; Imperial Cabinet; Mechta, Borovinsk Co.; Uskovoe U. K.; Zauralsk M. C.; No. 1 and 2, Nijni Tagil Works; Northern Yenisei G. M. Co.; Putilov Works Co.; Yacolev Bros.; Savelev & Sons & Company.

The following dredges show 50 to 75% of the theoretical production: Tibo-Brinol, Neviansk Works; No. 1 and 2, Moscow Forest Co.; Verx-Isetskix; Alexandrov Co.; No. 1, 4, 5, 6, 8, 9, 10, and 11, Fedorov G. M. Co.; Nadesda, Borovinsk Co.; Alexandrov, Central Siberia Co.; Alexander-Ivanov-Savvinix A. A.; Solomirsk and Heirs Trchaninov; P. V. Mordin, two dredges.

The above classification shows that 5 dredges, or 7.8%, worked up to the theoretical production; 27, or 42.1%, to 75%; 18, or 28.2%, to 50 to 75%; 14, or 21.9%, to less than 50% of the theoretical production. Such a result can not be considered favorable.

In 1909 the number of dredges working up to full production did not increase, and, in view of the greater experience, this failure must be attributed to faults of construction. A measure of the economic working of a dredge is given by the relation between the value of the gold and platinum won and the expenses of production. In the absence of the latter, estimates may be guided by the normal expenses; these were worked out for the Urals at about $15,437, and for the Yenisei at about $19,553 by the Commission reporting on the Utility of Dredges in Russia.‡ In these expenses, amortization of the dredges, their installment, and the cost of the claims, are not taken into account. Gold is valued at $18.08 and platinum at $22.48 per ounce. On this basis the following dredges worked profitably: Platinum Co. (2); Heirs of Count P. P. Shuvalov (2); Bogoslovsk Co. (1); Neviansk Works (6); Moscow Forest Co. (2); Verx-Isetskix Works (1); Alexandrov Co. (1); Tr. Savelev & Co. (1); Spassky Co. (1); Yacolev Bros. (1); Fedorov G. M. Co. (7); Draga Co. (7); Borovinsk Co. (2); Central Siberia Co. (2); Savvinix A. A. (3); Northern Yenisie G. M. Co. (1); Uskovoe U. K. (1); Zauralsk M. Co. (1); Nijni Tagil Works (2); total, 44.

Thus 44, or 70% of all the dredges constructed, should have worked profitably. However, the returns of the dredge owners do not give such brilliant results; this is accounted for on the one hand by the royalties paid to the owners of the claims, and on the other hand by the excessive general expenses. If the amortization of the cost of the dredges and the preparatory expenses be taken into account, the results are still less brilliant. The average cost of fitting up a claim for a 7-ft. dredge, including costs of buildings, supplies, and preparatory work, may be assumed at $77,185. For commercial success of such an enterprise the amortization shond be taken yearly at 10% of the cost. Hence the value of the precious metals extracted should be: In the Urals, $23,156; in the Yenisei, $27,272; in Eastern Siberia, $30,874. Under these conditions the following dredges have made a profit: Platinum Co. (2); Heirs of Count P. P. Shuvalov (2); Neviansk Works (2); Moscow Forest Co. (2); Alexandrov Co. (1); Tr. Savelev & Sons (1); Spassky Co. (1); Yacolev Bros. (1); Fedorov G. M. Co. (4); Draga Co. (1); Borovinsk Co. (1); Central Siberia Co. (1); Savvinix A. A. (1); Northern Yenisei G. M. Co. (1); Uskovoe U. K. (1); Zauralsk M. Co. (1); Nijni Tagil Works (2).

In all, 25 dredges, or 40% of all, have made a profit. If attention is given to the royalty paid (especially heavy in the Yenisei district) several dredges must be excluded from the above list.

These disquieting results account for the coolness felt toward the dredging industry. The profitable working of dredges depends as well on the amount of the precious metals in the material dredged as on the technical conditions. According to the data given by the above-mentioned Commission, in order to repay the expenses for running a dredge, not counting amortization, of fitting up the claims, it is necessary to work ground that contains, per cubic yard:

	Urals. (Cents.)	Yenisei. (Cents.)
For dredges with 4-cu. ft. buckets	9.10	11.59
" 5 "	8.13	10.28
" 6 "	7.21	9.25
" 7 "	6.50	8.51

The following table shows the amount of gold per cubic yard needed to repay the expenses when amortization is allowed for:

Bucket Cap. cu. yd.	Urals.	Western Siberia.	Eastern Siberia.
	(Cents per cubic yard.)		
2	22.96	28.04	32.72
4	15.15	17.96	20.40
4½	13.77	16.25	18.43
5	12.18	14.35	16.24
6	10.59	12.62	14.14
7	9.55	11.56	12.98

Such or a greater amount of gold has been obtained by the following dredges: Platinum Co. (2); Sosvinsk Co. (1); Heirs of Count P. P. Shuvalov (2); Bogoslovsk Co. (1); Neviansk Works (4); Lobvinsk Co. (1); Moscow Forest Co. (2); Alexandrov Co. (1); Tr. Savelev & Co. (1); Spassky Co. (1); Yacolev Bros. (1); Fedorov G. M. Co. (10);

‡*Mining and Scientific Press*, May 7, 1910.

Draga Co. (1); Borovinsk Co. (3); Central Siberia Co. (2); Savvenix A. A. (3); Northern Yenisei G. M. Co. (1); Tetiarsk G. M. Co. (1); Uskovoe U. K. (1); Mordin P. V. (2); Zauralsk M. C. (1); Nijni Tagil Works (2); Novo-Udilsk G. M. Co. (1); Amgunsk G. M. Co. (1); total, 46.

Hence there are 46 dredges, or 72%, extracting material whose tenor of precious metal is such that these dredges ought to be commercially profitable gold-mining enterprises. But many of the dredges in the above list are working at a loss; this can be entirely ascribed to technical faults.

Secondary Enrichment in Gold Veins

By R. L. Mann

There is one subject pertaining to practical mining which should be of great interest to those who prospect for and develop new properties; that is the rôle which erosion plays in relation to secondary enrichment. This subject has been but lightly treated in our time-honored textbooks, and only lately has it received a limited amount of attention. It is still held that the richest zone of secondary concentration in gold-bearing veins is at or close to the surface. The reason given for this is that surface waters have little effect on the solubility of the gold. Since time, however, is unlimited in nature, it can not influence the result, and atmospheric waters, given the right conditions, can and do in many instances completely dissolve the gold in the upper portions of veins, leaving nothing but a mere trace of the precious metal. These enriched solutions filter downward in the vein and deposit the gold at or close to water-level. During the time that this occurs climatic conditions must be ideal for the accomplishment of this leaching process; that is, warm with just sufficient precipitation at long intervals to supply the moisture for leaching, but not enough to favor rapid erosion. This may be called the first stage of surface alteration. The second stage begins when through terrestrial causes the climate changes. A cold or a torrid climate with frequent torrential rains favors rapid erosion, which, acting on the outcrop, removes the upper barren portion down to the enriched zone, which now becomes the surface. There remains a vein the upper portion of which is the richest, although the climate may have changed again. Should, however, the climate remain nearly constant after the leaching process, an impoverished outcrop will result. Any vein showing in the quartz on the surface the former presence of sulphides in the form of casts or cavities, but without gold in profitable amount, is very favorable for an enriched zone at a lower level. Massive white blocky quartz, showing no trace of former mineralization, does not fall under this heading, since secondary enrichment depends on primary mineralization.

A good case in support of the above contentions came to my notice in Idaho. The outcrop consisted of a white porous quartz resembling scoria without even a stain of iron oxide. The cells in the quartz were perfectly clean. Assays gave a trace in gold. The vein was tapped by an adit 50 ft. below the outcrop. Here the cells in the quartz were partly filled with iron oxide, and assays gave $20 per ton in gold. This gold was free but fine flour gold. Another adit tapped the vein 20 ft. above water-level and 150 ft. below the outcrop. The cells in the quartz here were completely filled with oxide of iron; the gold was coarse and free and averaged $45 per ton. The wall-rock is uniform in composition from the surface.

In my opinion, too much stress is laid on outcrop enrichments in gold veins. A miner will cheerfully sink through a barren iron gossan with only a few copper stains to encourage him in hope of finding rich ore below, but he looks with apprehension on a nearly barren white cellular quartz outcrop, even if it is in a known gold-bearing district. If gold can be dissolved slowly by sulphuric acid, generated by the oxidizing of the sulphides, then the only factor to be taken into consideration is time—and time in nature cannot be measured.

Monazite

By A. L. Sweetser

Until a few years ago monazite was considered a rare mineral of no commercial importance. When the incandescent properties of the oxides of cerium and thorium were discovered they were utilized in the manufacture of incandescent gas-mantles. Monazite, which contains these oxides, became of commercial importance and deposits of it were sought. Monazite is widely distributed throughout the United States, but only a few deposits have been found large enough to be of commercial value. These chiefly occur in North and South Carolina, Georgia, and Idaho.

This mineral occurs chiefly in gneisses and schists of Archean age. Only the gravel deposits from these rocks can be profitably worked, as they can be handled on an extensive scale by sluicing and washing. The color of monazite varies from a light yellow to reddish and even greenish yellow. It possesses a vitreous lustre, and is translucent, brittle, of a conchoidal fracture, and crystallizes in the monoclinic system. A simple test for monazite is to dissolve the substance in sulphuric acid, filter off the residue, and then add a little oxalic acid, which causes a precipitate to be formed. On igniting, this precipitate becomes a brick-red color, due to the presence of the oxide of cerium.

The commercial deposits occur in gravel beds of streams, and the distribution of the monazite is richer near bedrock, as in the case of all heavy minerals. The soil and gravel are washed into shaking hoppers and then through sluice-boxes, the oversize being thrown out by means of a revolving screen, the sand being then fed to Wilfley tables. In some cases a rough concentrate is obtained and the product is then reconcentrated. The concentrate from these mills contains sometimes as high as 80% monazite. The concentrate must then be dried, two methods being in use. Small producers spread the concentrate in a thin layer on an oiled cloth and the sun's heat removes the moisture. The larger companies use drying furnaces. A traveling belt then carries the dry concentrate, in a thin layer, beneath a large horseshoe magnet which removes the magnetite. The other minerals are removed by electrolytic-magnetic separation. The final product then contains about 98% of monazite and represents the sand that is shipped to the manufacturers of incandescent lights. In the reduction of monazite a large number of by-products are obtained, one of which is the oxide of didymium. This is of a dark-brown color, and a nitrate solution made of it is used to brand incandescent gas-mantles. Another mineral often associated with monazite is zircon, in the form of small, clear crystals with a brilliant lustre. Zircon is used in the manufacture of the Nernst lamp. The final process in the treatment of the monazite sand to remove the thorium and cerium, is a commercial secret and requires four months to render the thorium sufficiently pure for use in gas-mantles.

The cheaper gas-mantles are made with cheap grades of cotton, but the best use only Egyptian cotton. All traces of grease are first removed from the cotton by immersing it in large tanks filled with distilled water and ammonia. After agitating for some time with mechanical devices the cotton is removed and drawn through rollers to remove the excess water and then dried by revolving fans. Knitting machines then make network cylinders which are cut into strips long enough to make two mantles. These strips are then saturated in the 'lighting-fluid,' which consists of a solution of about 99% thorium and 1% cerium nitrates, in distilled water. The fabric is then dried, cut to the required lengths, and shaped on a form. The cotton fibre is then removed by heating the hood over a hot Bunsen-burner flame, leaving the thorium and cerium as a network. In order to protect this during transportation to the retail trade, the mantles are dipped in collodion and this collodion must be burned off before the mantle can be used for lighting purposes. Last year there were over fifty million mantles used in the United States.

Engineering Ethics

A committee consisting of H. M. Chance, F. L. Garrison, E. S. Hutchinson, R. A. F. Penrose, Jr., and R. H. Sanders, appointed by the Philadelphia Section of the Mining and Metallurgical Society of America, has submitted the following preliminary report, which is now being debated by various sections of the society.

Principles of Engineering Ethics

Many engineering functions are of far-reaching importance, involving matters affecting the health and safety of individuals, the welfare of communities, and the security of large investments, and it is therefore essential that the public should have entire confidence in the efficiency and integrity of the engineer and in his methods of thought and work. As the engineer is thus under obligations to maintain a standard of conduct in harmony with high ideals, it is right and proper to formulate a definite expression of these obligations, and,

Whereas, the Mining and Metallurgical Society of America, as stated in its constitution and articles of incorporation, aims to encourage high standards and to promote good fellowship among those professionally engaged in mining, metallurgy, and allied pursuits, it is therefore

Resolved, That the Society hereby recommends to those so engaged the adoption of the following precepts and principles. In so doing the Society has endeavored to present a statement of principles, the observance of which will promote the best interests of the profession and of those whom it serves. The endorsement of this summary is not intended to be exactly equivalent to its enactment as a code, but rather as the presentation of a suggestive and advisory document which may be useful to engineers in these and allied fields of activity. The word 'Engineer' is herein used to include those professionally engaged in mining, metallurgy, and allied pursuits, whether as engineers, chemists, geologists, metallurgists, managers, or superintendents.

Obligations of the Profession

1. *Maintain Dignity and Honor.*—It is the duty of the engineer to maintain the honor and dignity of the profession and of its members by all proper means.

2. *Criticism.*—Unnecessary criticism of others engaged in like work is detrimental to the interests of the profession.

3. *Membership in Societies.*—As an evidence of professional interest and of a desire to assist in placing the profession upon the highest plane, the engineer should, if possible, maintain membership in some technical or professional organization.

4. *Assistance and Consultation.*—If any work be beyond the ability of an engineer, his duty to himself, to the profession, and to his clients requires him to secure assistance to perform the service properly, or, if this be impossible, to decline the commission.

5. *Co-operation.*—The engineer should give freely of his knowledge and experience to other engineers, but when engaged in active competition, or employed by business rivals, such obligation cannot always be recognized.

6. *Good Fellowship.*—The best interests of the profession require that each should extend to every other member kindly and courteous consideration. Employment by business rivals should not prevent friendly relations between engineers, for although fidelity to employers may require them to become partisans, it should not engender personal enmity.

7. *Litigation.*—As litigation between engineers is detrimental to the profession, differences which cannot be settled by personal negotiation should, if possible, be adjusted by arbitration.

8. *Retaining Fees.*—When uncertain as to payment for his services, the engineer should obtain a substantial retaining fee.

9. *Gratuitous Services.*—Performing professional service gratuitously, except for other engineers, or as an act of charity, should be discouraged as unprofessional, in that it tends to reduce the compensation of other engineers.

10. *Underbidding.*—The engineer should not bid a price for performing a service which will not be fairly remunerative, especially if other engineers are bidding for the same work, but an engineer may accept employment at an unremunerative price if the experience or other advantage gained may compensate for the inadequacy of the monetary consideration.

11. *Commissions.*—It is unprofessional to offer compensation for securing the selection of an engineer for any service, but this should not apply to fees paid to reputable employment agencies; and it is likewise unprofessional to demand compensation for performing such service for others.

12. *It is unprofessional* to accept presents, fees, commissions, or compensation of any kind from those with whom the engineer transacts business for an employer or client.

Duties to the Public

13. *Protect Against Fraud.*—It is the duty of the engineer to discountenance the promotion of fraudulent schemes, and the exploitation of visionary processes and projects.

14. *Loyalty vs. Duty.*—When loyalty to employer or client conflicts with the engineer's sense of duty, he must be guided by his own judgment; but so long as he remains in the employ of another, or is retained in an advisory capacity, his first duty is to such employer or client. If the performance of this duty cannot be reconciled with proper observance of his obligations to the profession or the public, his connection with such employer or client should terminate.

15. *Reports.*—In the preparation of reports likely to be used for publication, the engineer should be careful to make all important statements in precise language. If a report is to be published, the engineer should have the right to revise the proofs prior to publication; if a portion only of the report is to be published, it is important that the engineer insist upon and exercise this right.

16. *When Engineer Is Interested.*—If an engineer be asked to report upon a property in which he is interested, or to undertake any work when he has an interest at variance therewith, he should state the facts to his client before accepting the commission, and if such report is to be used publicly, a statement of these facts should be embodied in the report, or his interest should be indicated in some equally effective manner.

Relations to Employers and Clients

17. *Devotion, Diligence, Fidelity.*—The engineer owes to his employer or client diligence and fidelity in the execution of matters entrusted to him.

18. *Confidential Relations.*—While the knowledge and experience gained by the engineer are his personal property, merging with and becoming a part of his professional capital, he should guard with scrupulous care those business and technical secrets with which he may become familiar by reason of confidential relations with employer or client.

19. *The obligation* to serve his employer or client loyally and not to divulge his secrets or confidences, requires the engineer to decline employment from others in matters wherein knowledge of such secrets or confidences will adversely affect the interest of said employer or client; in many cases such obligation may be held to exist after the termination of relations with said employer or client. The same obligation forbids the engineer from acquiring any interests that in the slightest degree may be adverse to those of his client.

20. *Expert Witness.*—When an engineer is called to testify as an expert witness, his duty will be completely discharged by fully and truthfully answering the questions put to him by the Court and by the attorneys in charge of the case. Although called upon to testify and paid for such testimony by one of the parties to the controversy, the engineer incurs no obligation to act as a partisan nor as an adviser to such party, unless it be distinctly under-

stood that he is called in as an adviser as well as an expert witness.

21. *Advisory Reports.*—In preparing advisory reports, the engineer should be careful to use language not readily capable of more than one interpretation, and plainly to distinguish between demonstrated facts and those hypotheses or matters of personal opinion which may have been factors in reaching the conclusions upon which his recommendations and advise are based.

22. *Contingent Fees and Contingent Interests.*—Experience has amply shown that an agreement by an examining engineer to accept a compensation or fee, the amount of which is contingent upon the nature of the report, or upon its value or usefulness in raising capital or in effecting the sale of a property, is likely to prove detrimental to the best interests of the engineer and of the profession. While some of the objections to such agreements do not obtain when all of the parties in interest understand and agree to the arrangement, the practice must always involve some risk to the reputation and standing of the engineer. In the development of mineral properties, if the employer or client desires to have the engineer personally interested in the outcome, such interest often may properly be made contingent upon the measure of success attained, but before making such an arrangement the engineer should be careful as to the character of those who will thus become his business associates, and should be sure of his ability to perform his part of the contract.

23. *Expert Witness Contingent Fee.*—The making of an agreement to accept for services as expert witness a fee which shall be contingent upon the result of the trial, may place the engineer in a painful and embarrassing position, entirely discredit his testimony, and seriously damage his reputation as an engineer. If such agreement be necessary, it should be made openly and not secretly.

24. *Duty to Warn.*—It is the duty of the engineer to give timely warning to employer or client of any matter that may threaten danger, loss, or damage to such employer or client; and further, to endeavor to reduce to a minimum all risks of loss or of damage to property, or of danger to life, from causes within his control.

25. *To Advise Adversely.*—When called upon to examine into any proposition, if, from a preliminary investigation, it appears that further examination is not warranted, the engineer should advise his client to drop the matter.

26. *To Assume Full Responsibilities.*—An engineer should not evade the responsibility of definitely advising his client for or against any project. In reaching his conclusions he should avoid being either too optimistic or too pessimistic. An over-enthusiastic engineer may lead a client into an investment that should not have been recommended, while an over-cautious engineer may keep a client out of a good investment by his excessive conservatism. While an engineer may often be unable to convince himself with absolute certainty that a project is good under existing circumstances, this doubt does not justify him in unqualifiedly condemning it, any more than the fact that it might possibly be good would justify a more sanguine engineer in unqualifiedly recommending it. If unable to reach a definite conclusion, he should explain to his client the conditions as they exist, and let him decide whether or not he will take the risk involved.

27. *Estimates of Quantities.*—In reporting upon the quantities and values of ore or mineral, the engineer should state with sufficient clearness the facts upon which the estimates are based, and the method adopted in making the computations.

28. *Fees, How Determined.*—The following paragraph defining the principles which should govern the engineer in determining what constitutes a proper charge for his services, is taken (with slight changes in wording) from Paragraph 12 of the Canons of Ethics of the American Bar Association: In fixing fees, engineers should avoid charges which overestimate their advice and service, as well as those which undervalue them. A client's ability to pay cannot justify a charge in excess of the value of the service, though his poverty may require a less charge, or even none at all. The reasonable requests of other engineers and of their widows and orphans without ample means, should receive special and kindly consideration. In determining the amount of the fee, it is proper to consider: (1) the time and labor required, the novelty and difficulty of the questions involved, the physical risks and discomforts, and the previous experience necessary, to render the required service; (2) whether the acceptance of employment in the particular case will preclude the engineer's employment by others in cases in which there is reasonable expectation that otherwise he would be employed, or will involve the loss of other business while employed in the particular case, or will produce complications with other clients or engineers; (3) the customary charges of engineers for similar services; (4) the amount involved and the benefits resulting to the client from the services; (5) the contingency or certainty of the compensation; (6) the character of the employment, whether casual or for an established, constant client; and (7) whether the character of the employment is such as to be beneficial or detrimental to the engineer. No one of these considerations is in itself controlling. They are mere guides in ascertaining the real value of the service.

29. *Controversies Over Fees.*—Controversies with clients over fees should as far as possible be avoided, and lawsuits resorted to only as a last recourse.

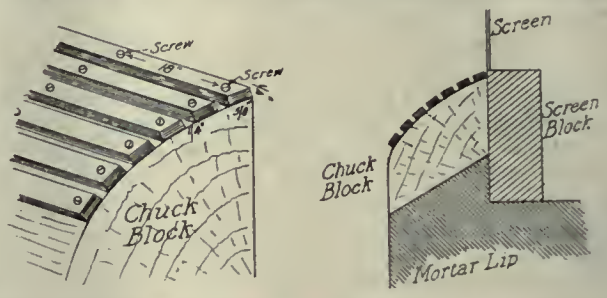
MacQuisten Tubes in Idaho

The Federal Mining & Smelting Co. has erected and put into operation 119 of the MacQuisten tubes at its Morning concentrating plant at Mullan, Coeur d'Alene district, Idaho. These tubes are manufactured by the American Direct Concentrator Co. of Salt Lake, and are designed to recover the metals from certain classes of ore which are difficult to treat by ordinary wet concentration. The process involves the reverse of gravity concentration, inasmuch as by this method the gangue settles, and the sulphide metal floats and overflows from receptacles. The ore taken from the Morning mine contains lead, zinc, and silver, associated with siderite and barite. The greater part of the lead is recovered by Hancock jigs, tables, and vanners; the tailing and part of the middling from the tables and vanners, consisting of a 40-mesh product containing zinc, siderite, and barite, are pumped to the tube plant, elevated to the top of the building and dewatered by Dorr and Akins classifiers, by which the moisture is reduced to 10 or 15%. It is then passed to storage tanks, and thence by discharge pipes to three distributers, the pulp from each distributer passing by gravity to a unit of 40 tubes, divided into five sets of 8 tubes each. Each tube consists of an iron cylinder, 7 ft. long, 8 in. diam., the interior surface being spirally corrugated. The tube revolves at about 30 r.p.m., and has a horizontal position. At one end is a receptacle into which the feed is received from the distributer; and this receptacle discharges into the tube, the feed end of which has an enclosing rim to keep the pulp from wasting. As the tube revolves the spirals carry the pulp and slime to the opposite end, discharging them into a 2-compartment iron settler; the compartment nearest the tube end contains a hopper-like outlet through which the settled gangue and its accompanying mineral pass to another receptacle, from which it is fed into a second revolving tube placed immediately below the first one. The spiral creases in the tube tend constantly to lift the particles of metal to the surface of the water, and the film of air which forms around each bright metallic particle causes it to float. When once afloat, the metallic substance is carried by the current of water over the first compartment into the second, and the water and slime overflow from the one into the other. The outlet at the bottom of the second compartment leads to a small tank which holds the concentrate thus recovered. The pulp and slime, before being introduced into the tubes, are passed through an acid bath containing 0.5% H_2SO_4. In addition to this the water in the circuit contains 0.05% H_2SO_4. It is explained by O. B.

Hofstrand, in charge of the work of putting in the equipment, that the percentage of acid used may be varied according to the character of the ore; that some particularly lustrous ores may require no acid at all. The purpose of introducing the acid is to cleanse the particles of ore and expose their surfaces so as to better induce flotation. Each stand is made up of eight tubes, or four pairs. The two tubes of the first pair are parallel, and are about 10 in. apart; in each of these, first concentration by flotation is performed. The second pair rest immediately below the first, and reconcentrate the tailing from the first pair. In like manner there is a third pair that re-treat the tailing from the second, and this is followed by a fourth pair in which is effected the final separation, the tailing from the last pair of tubes being pumped to Callow tanks, and the settled slime being put through other sets of tubes for the recovery of the finer particles of metal. The 15 stands of tubes in this plant are expected to treat 50 tons per day of table tailing and middling, the metal of principal value therein being zinc sulphide. This part of the plant was put in operation about May 10, and actual results on this class of ore are awaited with unusual interest. The first mill using MacQuisten tubes that was operated in this country was that of the Glasgow & Western at Golconda, Nevada, three years ago. Here the ore consisted of copper-iron sulphide in a gangue that was mostly epidote.

A Riffle Chuck Block

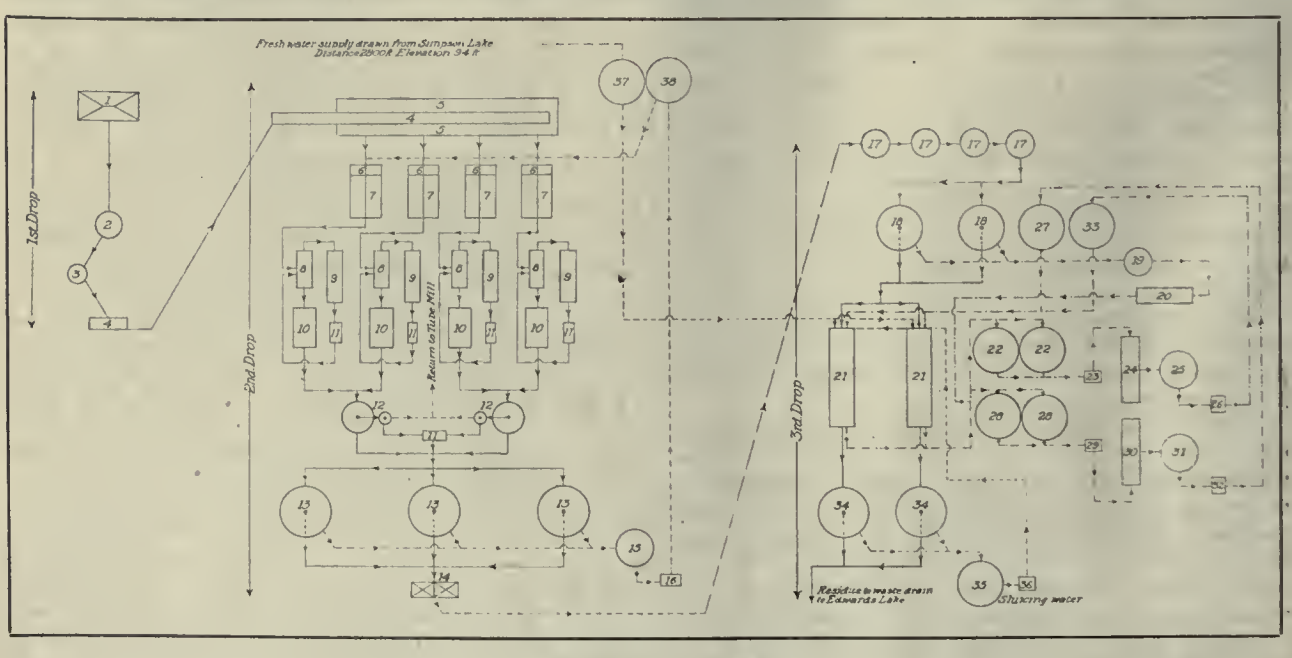
Chuck blocks of various shapes and material have been used as long as stamps. Ordinarily they are covered with copper plates and are depended upon to catch a considerable part of the gold recovered by inside amalgamation. Along the Mother Lode of California, as the stamps have



been speeded up, and more effort directed toward obtaining capacity, inside amalgamation has become less and less important. The chuck-block plate, being set immediately below the screen, is exposed to much wear and with heavy, rapid-dropping stamps has little chance to accumulate amalgam. A riffle plate has therefore come into use. One form is illustrated in the accompanying sketches.

The Dome Mill

Below is presented the flow-sheet for the 40-stamp mill now being erected for the Dome Mines Co., by the Merrill Metallurgical Co. It is of especial interest as being the first, other than experimental mills, to be erected in the Porcupine district of Ontario. The ore so far found has proved easy to treat. The figures in the illustration correspond to machines and data as below: (1) hoist; (2) Kenedy No. 7½ gyratory crusher; (3) Kenedy No. 5 gyratory crusher; (4) belt-conveyor to mill-bins; (5) battery storage-bin; (6) four 10-stamp batteries, 1250-lb. stamps, 102 drops per minute; (7) primary amalgamating-plates, 54 by 144 in., slope 1½ in. per foot, plates in two sections; (8) four duplex Dorr classifiers; (9) four 5 by 22 A. C. tube-mills, El Oro lining, scoop feed, spiral discharge, 31 r.p.m.; (10) secondary amalgamating-plates, 108 by 144 in., slope ½ in. per foot, in two sections; (11) five Frenier pumps, 8 by 54 in.; (12) two concentrating-cone units; (13) three Dorr thickeners, 30 by 10 ft.; (14) duplex bucket-elevator, centre to centre 70 ft., buckets 7 by 16 in.; (15) return battery-water sump, 20 by 10 in.; (16) return battery-water pump, Aldrich vertical triplex, 350 gal. per minute, 15-hp. motor; (17) four continuous agitators 8 by 40 ft.; (18) two Dorr thickeners 25 by 10 ft.; (19) thickener overflow tank 10 by 10 ft.; Merrill clarifying-press; (21) two Merrill slime-presses, 76 four-inch frames, Dome type; (22) two strong-solution precipitating-vats, 25 by 10 ft.; (23) strong-solution precipitation pump, Aldrich vertical triplex, 175 gal. per min., 7½-hp. motor; (24) strong-solution (Merrill) precipitation-press, 52-in. press, 20 two-inch frames; (25) strong barren-solution sump 20 by 10 ft.; (26) strong barren-solution pump, Aldrich vertical triplex, 175 gal. per minute, 7½-hp. motor; (27) strong barren-solution storage-tank 25 by 10 ft.; (28) two weak-solution precipitating-vats, 25 by 10 ft.; (29) weak-solution precipitation-pump, Aldrich vertical triplex, 100 gal. per minute, 5-hp. motor; (30) weak-solution (Merrill) precipitation-press, 10 two-inch frames; (31) weak barren-solution sump, 20 by 10 ft.; (32) weak barren-solution pump, Aldrich vertical triplex, 100 gal. per minute, 5-hp. motor; (33) weak barren-solution storage-tank, 25 by 10 ft.; (34) two Dorr thickeners, 30 by 10 ft.; (35) sluicing-water sump, 25 by 10 ft.; (36) sluicing-water pump, Aldrich vertical triplex, 700 gal. per minute, 50-hp. motor; (37) fresh-water storage-tank, 25 by 20 ft.; (38) battery-water storage-tank, 25 by 10 feet.



Flow-Sheet, Dome Mill.

Texas Coal Production

William B. Phillips, director of the Bureau of Economic Geology and Technology of the University of Texas, has collected statistics of the production of coal and lignite in Texas for the year 1910. These may be summarized as below:

The production of coal was 1,128,947 short tons, valued at $2,829,389, or an average value, at the mines, of $2.51 per ton, an increase of 14c. per ton over the average value in 1909. In 1908 these figures were 1,047,407 tons, valued at $2,580,991, and in 1909 1,144,108 tons, valued at $2,714,630. During the last ten years the total production of coal has been 8,844,207 short tons, valued at $19,576,335. The coal-producing counties are: Erath, Jack, Maverick, Palo Pinto, Parker, Webb, Wise, and Young. The Rio Grande coalfield, comprising the counties of Maverick and Webb, produced, in 1910, 215,328 tons, valued at $503,867, or $2.34 per ton. The North Central coalfield, comprising the counties of Erath, Jack, Palo Pinto, Parker, Wise, and Young, produced 913,619 tons, valued at $2,325,522, or $2.55 per ton. In 1910 the production of lignite was 979,232 short tons, valued at $941,700, or an average value per ton, at the mines, of 96c. The average value per ton increased over that for 1909 13.2c. The 1910 production was by far the largest in the history of the industry. In 1908 the production of lignite was 847,970 tons, valued at $838,490. In 1909 it was 715,151 tons, valued at $592,421. The lignite-producing counties are: Bastrop, Fayette, Hopkins, Houston, Leon, Medina, Milam, Rains, Robertson, Van Zandt, and Wood. The total production of lignite during the last ten years has been 5,311,902 tons, valued at $4,718,841. The total production of coal and lignite during the last ten years has been 14,156,109 tons, valued at $24,295,176.

The Nakanosawa Gold Mine

By Yoshikatsu Yamaguchi

This mine is situated in a state forest at Tosawa, Sankawa village, in the province of Yechigo. It is five miles from Kamikoya on the highway to the city of Aizu from Yechigo, this being the most convenient road, although there are several. At the mine there are several excavations of unknown age. In 1905 they were examined and found to contain rich gold ore, since which many rich quartz veins have been discovered in different places as the result of exploration. The metallurgical treatment of gold ores was commenced in 1907, and bismuth ore was discovered a year later. The mine is 1150 ft. above sea-level, in the valley of Nishito, a branch of the Nakanosawa valley. The present underground workings are open to a depth of 350 ft. In the vicinity of the mine there are many outcropping veins, and there is also an old mine where molybdenite was worked. A high peak east of the mine consists of old granite. The area about the mine is covered with Tertiary tuff and later liparite. The liparite chiefly forms the peaks of the district, while the tuff predominates in the basins. The two rocks can not be easily distinguished on account of their having undergone extensive metamorphism. The gold veins usually occur only in the liparite. Molybdenite is frequently found forming fissure veins in granite. Somewhat larger veins of gold and bismuth ore may be divided into two vein groups, those striking northeast and those trending north. The veins have various widths, from 0.05 to 0.3 ft., and frequently over 2 ft. The larger veins now being worked number 15, and extend about 200 ft. Three of these have been followed in depth for more than 120 ft. Five veins are now being explored.

In the Yamanokami vein old workings are found containing much quartz, and the weathered country-rock contains gold. Throughout the country-rock in certain places there are many veins and veinlets, most of them having not as yet been explored. The same occurrence is seen wherever the rock is uncovered over an area of 25 acres, including Tosawa and Sangaitaki, the most important portions of the mine. The minerals found in the form of veins and impregnations, are quartz, pyrite, chalcopyrite, and bismuthinite, frequently intermixed with mica in small quantities. The parts of the veins which are rich in chalcopyrite are workable for auriferous copper ore. Bismuth is found in almost every vein. The bismuthinite is fibrous and usually of lead-gray color. It is associated with quartz, pyrite, and chalcopyrite. It occurs usually in the lower part of the veins instead of in the upper, and in certain stopes in the No. 2 and No. 6 veins. The bismuth oxide is fine granular with grayish-white lustre, or white and earthy, or massive. It is intergrown with quartz and chalcopyrite. This is especially the case with the No. 4, the No. 5, and the No. 13 veins, and the Yamanokami vein.

In all the veins gold is included in the minerals. From its mode of occurrence, both primary and secondary gold seems to be distinguishable. Much of the ore contains 0.01 to 0.1% gold. Nearly every vein has at least one bonanza, its length being sometimes one-fifth or one-third of the length of the vein. Generally the bonanza is also rich in bismuth. The total depth of the present workings is 300 ft. between the highest level of the Sanjin vein, 1120 ft. above sea-level, and the No. 3 level of the No. 1 vein. There are 30 levels open in an area of 500 by 600 ft. Eighteen samples of the ore were taken from the important veins and assayed, the results showing that they contain 0.0002 or 0.0003 to 0.02% or 0.05 to 5.8 oz. gold per ton of 2000 lb.; the first figures indicate the contents of three samples only. The gold and bismuth content of the ores taken from the several places is as follows:

	Gold. Per cent.	Gold. Oz.	Bismuth. Per cent.
Average from old workings	0.0034	0.69	.....
Bi and Au ore of the Sanjin vein	0.0286	8.44	3.17
Rich ore from No. 4 level	0.0436	12.72	.....
Rich Bi ore dumped outside stamp-mill	0.0006	0.17	20.00
Bismuth sulphide ore in middle level	....	.....	16.32
Rich gold ore containing bismuth oxide in No. 13 level	0.0746	21.75	27.86
Bi ore (chiefly oxide) from middle of No. 2 level	....	.....	35.43
Bi ore of No. 12 level	0.0190	5.54	5.33

The ores subjected to cyaniding (January 1909) had the following gold content: Rich ore, average, 0.0428% or 12.49 oz. per ton; medium ore, 0.0066%, 1.92 oz.; poor ore, 0.003, 0.87 ounce.

The ores hitherto worked as gold ores have been bismuth oxide from higher portions of the mine, 220 ft. above the water-surface of the Nishisawa valley. In depth the amount of sulphide in the veins increases. Oxidized ores resulting from weathering are abundant, and are of great convenience in metallurgical treatment. The zone of oxidation extends 200 to 300 ft. in depth. The daily output of the ores is about 2.6 tons. The ore is carried down to the cyaniding mill by self-acting wire-rope tramways, where it is classified into lump and fine. The lump ore is crushed to a size of 1.2 to 1.8 in. and sent to the stamps, together with the fine ore. There are five Californian stamps, weighing 330 lb. each. They are driven by an 18-ft. water-wheel of an old Japanese type. The battery-screens are usually 40-mesh wire cloth. The apron-plates are in three rows, each of six amalgamated copper plates 1.2 ft. wide and 2 ft. long. Next, and below the copper aprons, *seriita* (concentrating boards) are used, covered with a woolen cloth. The concentrate is then treated by pan and barrel-amalgamation, while the tailing is sent to a small Wilfley table for the further separation of sulphide. The extraction of gold by amalgamation is 50% for the ordinary ore, and 80% for the rich ore. The sulphide concentrate from the Wilfley tables sometimes contain more than 0.003% (0.87 oz.) gold and 2 to 7% copper. The concentrate is smelted together with other auriferous copper ores. Repeated experiments on cyaniding the gold ores have given excellent results. How to utilize bismuth ores is now under investigation. A year and a half ago the mill was being enlarged, and since that time substantial progress has probably been made.

Western Australia Ore Reserves

Save a couple of companies, ore reserves in the Kalgoorlie mines are only published at the end of the year. Below is a review of the situation at the end of 1909 and of 1910, no account being taken of 'probable' ore.

	Dec. 31, 1909.		Dec. 31, 1910.
Name.	Tons.	Value.	
Associated	483,517	$10.08	Doubtful quantity. Plenty of $5 ore.
Associated Northern	.....	.....	Impossible to estimate.
Chaffers	20,000	9.60	Past year's average, $6.50.
Golden Horse Shoe 1,071,638		10.33	French engineer estimates 750,000 tons at $8 per ton.
Golden Ridge...	60,000	11.52	May be lower account of 500-ft. level.
Great Boulder Perseverance.	380,772	6.60	Mine should continue so.
Great Boulder Proprietary...	751,077	16.32	Bottom levels not estimated.
Great Fingall..	49,460	6.00	The 17th winze may have opened a good deal of ore.
Hainault	100,000	6.96	Indications point to a similar reserve.
Ivanhoe 1,007,798		10.96	Tonnage should be maintained, though ore a little lower in value.
Kalgurli	400,000	12.30	Management does not commit itself to a strict estimate.
Lake View & Star	172,050	6.68	Star leases should keep up average.
Oroya Black Range	107,000	10.08	Will probably be maintained.
Oroya Links...	84,000	8.40	Much development to keep this up.
Sons of Gwalia.	513,000	8.40	Should easily be kept up.
Sons of Gwalia South	61,000	9.73	Estimate this year likely to be lower.
South Kalgurli.	156,939	7.12	Should be much as before.

Late in 1908, and during 1909, the Oroya Links, Lake View & Star, and Chaffers-Main Reef consolidations were made. Large areas of country that could not be profitably worked as separate concerns, were absorbed or merged. The Lake View & Star seems likely to be the one that will be most profitable. Many tributers are in the Oroya Links mine, and active development is under way to open up more ore. It is difficult to predict its future.

Water Diviners in South Africa

The Springs Mines, Ltd., in Far Eastern Rand has been shaft-sinking for over a year, but owing to the bad ground and water encountered, the depth is only about 700 ft. Better strata have, however, now been reached and improved progress is confidently anticipated. As an instance of the dread in which the dolomite—a kind of caverned and jointed magnesian limestone—is held, the appointment of a water diviner by the Daggafontein Gold Mining Co., Ltd., to point out a position for the shafts where water would be avoided ought to be mentioned. Hitherto water diviners have been employed to show where an abundance of water exists, and it seems rather a novel idea for a water diviner to be called upon to show where there is no water underground. Needless to say, the water diviner completely failed to indicate a suitable spot, and the shaft is flooded with water just as though his services had never been called in. There is a feeling that unless circular shafts are sunk and these heavy flows of water shut out, the Far East Rand goldfield will afford several instances of shaft-sinking failures where any thickness of dolomite has to be pierced. At Modderfontein a circular shaft is being sunk, but although it is in the same field dolomite can scarcely be expected to be present. The circular shape has apparently been selected to promote ventilation, and because the consulting engineer, a coal mining engineer from South Wales, has been accustomed to circular shafts. The selection of this shape is giving rise to considerable discussion.

Utah Copper

The annual report of Utah Copper for the year ended December 31, 1910 shows the total production to have been 89,019,511 lb. of copper at a cost of 8.069c. per pound. Of ore mined, 82% was by steam-shovels and 18% through underground workings from the Boston property. The average cost of mining was 40.97c. per ton, of which 13.3c. was charged to development and stripping expense, leaving the total cost for production 27.67c. per ton. The cost per pound of copper stated includes smelting, refining, transportation, and selling expense, and compares with 8.787c. per pound for 1909. The report states that the company's ground in Bingham contains 203,500,000 tons of fully and partly developed ore. Of this, 152,130,000 tons is said to be fully developed and blocked out. Of the fully developed ore, it is stated, 60,000,000 tons have an average copper content of 2%, and the remaining 92,130,000 tons have an average copper content of 1.6%. The Bingham & Garfield railroad, for transporting the company's ores twenty miles from Bingham to the concentrators and smelters at Garfield, will be in operation by July 1. The average price received for copper during 1910 was 12.672c. per pound, as against 12.915c. per pound in 1909. The old board of directors was re-elected at the annual meeting. The Utah Copper has bought the Pay Roll group of 175 acres, filling in a stretch between its original holdings and the old Boston Consolidated territory.

New Mill at Great Boulder Perseverance

The Great Boulder Perseverance gold mine at Kalgoorlie is once more on its feet after having recoverd from its second attack of illness. The first blow it, or at least the shareholders, received was in 1902 when its rich ore suddenly gave out and it became very lean. The energies of Hooper & Speak, the new engineers, were equal to the occasion and put the mine in order. The second adverse episode was the fire in November 1909. The main driving engine, the air-compressors, Griffin mills, Edwards roasting furnaces, and their subsidiary equipments were entirely lost. Rebuilding was commenced immediately and Krupp dry ball-mills were substituted for Griffins. The rebuilt plant went into commission on August 1. During the idleness of the mill development work was actively continued at the mine. The main shaft reached a depth of 2228 ft. by April 1911. A new level has been opened at 2050 ft. where profitable ore has been found in the south drift and cross-cuts are being driven at 2200 ft. On December 31 the reserve consisted of 120,134 tons of broken ore in the stopes (shrinkage stoping being the method employed), with contents averaging 6.55 dwt. per ton, 362,700 tons of proved ore averaging 5.95 dwt. and 289,380 tons of probable ore averaging 5.08 dwt., a total of 772,214 tons, as compared with 629,852 tons the year before. During the five months, August to December, 91,852 tons was milled, yielding 27,013 oz. gold and 3408 oz. silver, having a total value of £115,083. The extraction of gold was 79%, but as gold is always locked up on starting a new plant this figure will improve later. The capacity of the plant is 20,000 tons per month and the maximum is determined by the capacity of the roasting furnaces. During the time the mill was running the working costs averaged 19s. 1d. per ton, and were reduced from 24s. 2d. in August to 18s. 3d. at the end of the year, but owing to the expense of development and management continuing during the rebuilding of the mill, the result of the work during 1910 has been a loss of £20,913. The balance sheet shows an item, "Addition to plant machinery and buildings during 1910, £44,636," and on the other side, "Bankers' overdraft and interest, £42,650." This, together with the announcement made a year ago that £20,000 had been recovered from the insurance company, explains the method of financing the rebuilding of the plant.

Discussion

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

Surface Indications of Ore-Shoots

The Editor:

Sir—A protracted field season has delayed until now my opportunity to participate in the discussion evoked by W. H. Storms' interesting article in your issue of October 22, but perhaps I may be permitted, even at this late date, to offer a few points for consideration.

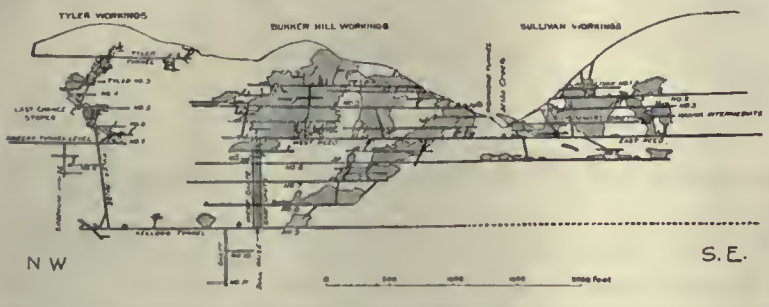


FIG. 1. LONGITUDINAL VERTICAL PROJECTION OF THE BUNKER HILL & SULLIVAN MINE.

That ravines which cross the outcrop-line of a vein are in many instances the topographic expression of transverse faulting subsequent to ore deposition, and that accordingly they suggest underground disturbance of a kind likely to destroy the continuity of the orebody and perplex the miner may readily be granted; but whether this relation is so constant as to be properly termed a law is a question requiring critical examination. The conditions involved are, it appears to me, far more complex than has been recognized in the present discussion, and it may be doubted whether generalization from a few districts suffices in this case to establish an invariable rule or even to furnish a generally reliable guide to the prospector or miner. With the hope of enlarging the scope of the inquiry I shall try to present some factors that appear to preclude a simple solution of the problem. The occurrence of ore-shoots in a number of well-known mines is illustrated in the accompanying figures taken from various published reports of the U. S. Geological Survey.

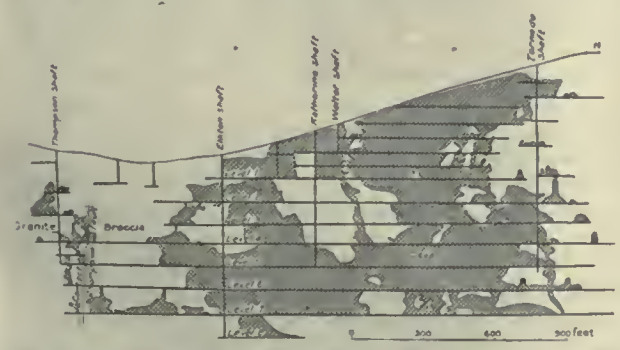

FIG. 2. GENERALIZED LONGITUDINAL SECTION OF THE ELKTON MINE, CRIPPLE CREEK, COLORADO.

In the first place, the facts open to direct observation are to some extent weighted in favor of Mr. Storms' suggestive hypothesis. Veins ordinarily are discovered on the hills, not in the gulches, and the normal course in the development of a mine is the exploitation, by tunnels or shallow shafts, of the ore-bearing ground above the local drainage lines, while deep shafts and pumping are deferred until a comparatively late stage. Consequently, longitudinal sections of many mines show more extensive stopes in the ridges than under the gulches, this arrangement of the workings being quite independent of the actual distribution of the ore. This fact scarcely needs special illustration here, but it may be remarked that the Bunker Hill & Sullivan mine, cited by Mr. Storms in support of his view, is partly at least illustrative of this normal course of development (see Fig. 1), although I admit that as it is about seven years since my examination of the mine was made, I am unable to state from present knowledge whether subsequent development has confirmed the opinion then generally held that the Sullivan ore-shoot pitches northwest under Milo gulch.

In the second place, the facts relating to the distribution of the ore with reference to cross-gulches are in many instances inconclusive, and might be as well cited against as for the supposed rule. In the case of the Elkton mine at Cripple Creek (Fig. 2) and the Helena-Frisco mine (Fig. 3) in the Coeur d'Alene district, for example, the suggested law is not quite clearly applicable. A large number of veins, moreover, contain orebodies in precisely those portions where according to the hypothesis discussed they should be barren, or at least should exhibit a marked change in tenor. The Mary McKinney mine at Cripple Creek (Fig. 4), which Mr. Storms, by the way, cites in favor of his generalization, was stoped extensively under the south branch of Arequa gulch, and it does not appear to me that the Cripple Creek district shows any systematic connection between cross-gulches and lack of ore. The same may be said of the Coeur d'Alene district, where the principal stopes of the Tiger-Poorman mine are directly under Canyon creek. The Georgetown district affords some excellent examples of large orebodies under cross-gulches, as shown by Fig. 5 to 7, taken from Professional Paper No. 63, by Spurr, Gar-

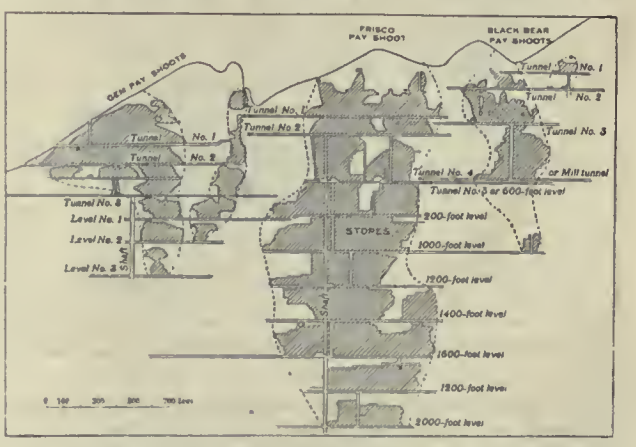

FIG. 3. LONGITUDINAL SECTION THROUGH THE HELENA-FRISCO MINE, COEUR D'ALENE DISTRICT, IDAHO.

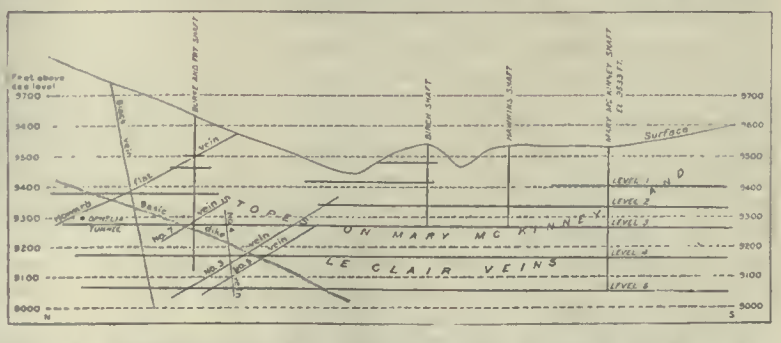

FIG. 4. GENERALIZED LONGITUDINAL SECTION THROUGH THE MARY McKINNEY MINE, CRIPPLE CREEK, COLORADO.

rey, and Ball. The Stanley mine near Idaho Springs has a pay-shoot that extends across the valley of Clear creek, and E. S. Bastin, who has been studying the veins of the Central City quadrangle, informs me that the orebodies occur as commonly under the gulches as elsewhere. At Bisbee, where the deposits, it is true, are not veins, there

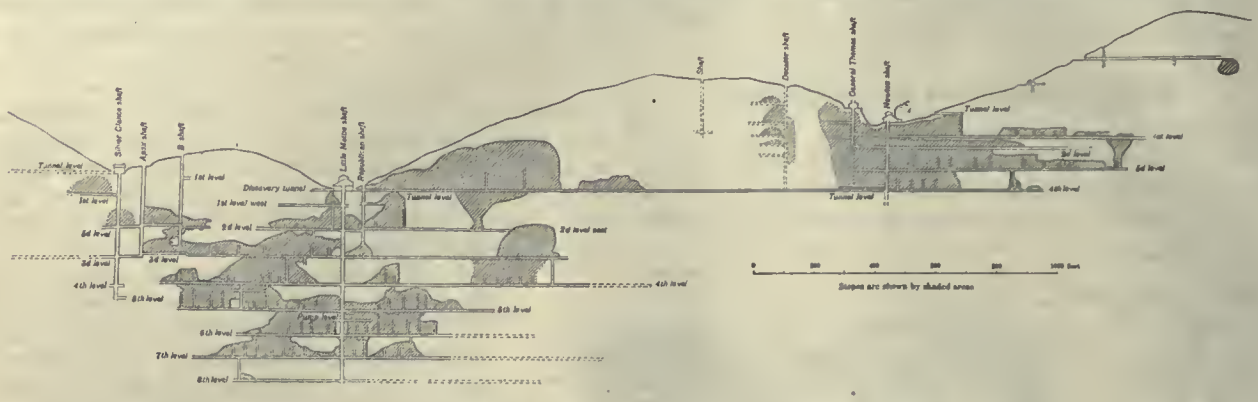

FIG. 5. LONGITUDINAL PROJECTION OF THE LITTLE MATTIE WORKINGS, IDAHO SPRINGS, COLORADO.

is a decided prevalence of orebodies under topographic depressions. Exceptions to Mr. Storms' rule might undoubtedly be found in considerable number by searching through the literature descriptive of ore deposits, but probably sufficient examples have been adduced to show that it certainly is far from being universal. With these facts in

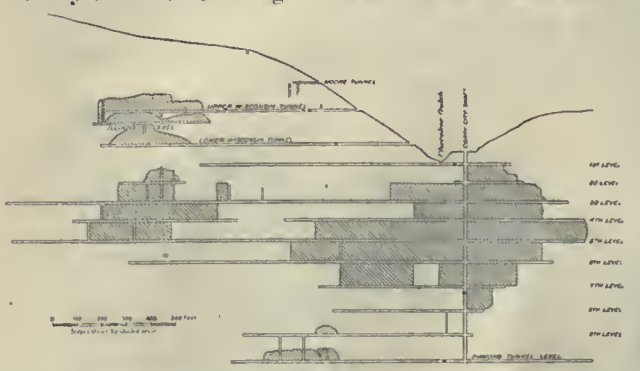

FIG. 6. LONGITUDINAL SECTION OF THE WISCONSIN-CORRY CITY WORKINGS, GEORGETOWN DISTRICT, COLORADO.

mind, a consideration of the conditions controlling the development of transverse gulches will be in order.

Inasmuch as the ravines are cut by erosion, their courses in a general way are determined by structural or textural weakness in the underlying rock. This determining factor, however, may be neither direct nor local. In other words, although a stream may follow a course that as a whole is determined by ease of erosion, yet there is a limit to its minuter adjustments to varied resistance, and at certain places the stream may cut through rocks of exceptional hardness where such obstacles are less formidable than would be a change of channel. Thus it is not safe to conclude that a gulch is necessarily coincident at every point with a line of underlying weakness, and it follows from this that the place where a ravine crosses a vein may have no connection whatever with the structure or character of the vein at that particular place. Along the Mother Lode belt, which Mr. Storms knows so well, the relation of erosion to the veins and their enclosing rocks is exceptional. The Mother Lode itself is a remarkably continuous chain of hard massive quartz veins that run nearly parallel with narrow belts of steeply inclined laminated rocks of a wide range in hardness and durability. The region has a well adjusted drainage of dominantly consequent type, that is the main streams flow down the slope in consequence of its general westerly tilt. They thus traverse the strike of the rocks and are fed by subsequent branches well entrenched along belts of weak rocks. Under these circumstances the Mother Lode veins, as a rule, stand out as ridges, and the conclusion that where the streams cross these the searching action of erosion has found a weak spot in the rampart is a fairly safe one. The condition of weakness may be transverse faulting or may be lack of quartz deposition at a place where the fissure pinches. If faulting has taken place, whether the dislocation is older or younger than the period of ore formation should at least be determined before drawing conclusions as to its economic effect. If the dislocation is partly or wholly older than the period of original deposition or of enrichment (if present), then Mr. Storms' rule may apply, although not infallibly. If the faulting is entirely later than the ore the existence of the gulch may suggest that the miner may have trouble in picking up the dissevered parts of his vein, but it does not indicate absence of ore. If the gulch marks a pinch in the vein, of course, as a rule, there will be little ore at that place. Along the Mother Lode the ore is generally associated with, if it does not occur within, hard masses of vein quartz. Not all veins are of this character, however. In some districts the productive portions of the veins are softer and weather more readily than the barren portions. In such a case a transverse gulch, if it depends upon underlying structure at all, is more likely to coincide with a rich than a poor part of the vein. Many of the deeply worked veins of Clear Creek and Gilpin counties, Colorado, appear to illustrate such conditions. Other factors to be considered in attempting to set up a general rule are downward enrichment and ground-water level. If, for example, a vein owes its importance to downward enrichment and is situated in a humid country where the level of the ground-

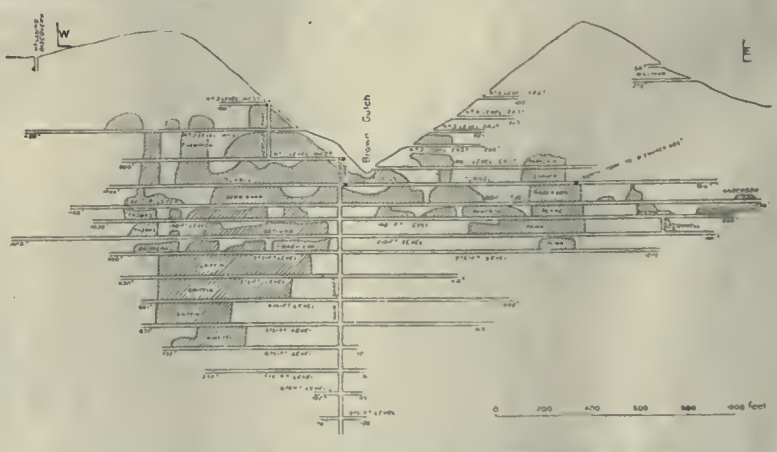

FIG. 7. VERTICAL PROJECTION OF SEVEN-THIRTY WORKINGS, GEORGETOWN DISTRICT, COLORADO.

water is high and has not been subject to great fluctuation, then it is possible that the bottom of a cross-gulch may have been cut down into the unenriched sulphides, while the ridges on one or either side contain good ore, as illustrated by some of the veins at Breckenridge, Colorado. On the

other hand, if the region is an arid one, the gulch may mark a soft and readily permeable part of the vein where the enriching action has been especially active.

I realize that the foregoing suggestions by no means exhaust the factors that should be taken into account in attempting to frame a general law to cover a supposed significant relation between cross-gulches and pay-shoots, but elaborate treatment would take too much of your space, and perhaps enough has been said to show that while Mr. Storms' rule may serve to indicate the probabilities in a district where the relation between ore deposition, faulting, and erosion are clearly understood to have a certain constant character, it is not of universal application and is probably not infallible even in any one district.

F. L. RANSOME.

Washington, D. C., May 1.

American Metallurgical Society

The Editor:

Sir—In an editorial of May 6 you express very pessimistic views regarding the future of the American Metallurgical Society which was recently organized in this city by "a few brave spirits." The society has just issued a call for charter members, and as there is a likelihood of many of the engineers who read your editorial forming a similar opinion without being fully conversant with the movement, to the great injury of the society, I shall ask of you the privilege of presenting to them a few facts regarding the society and what it proposes to accomplish.

The American Metallurgical Society was incorporated under the laws of this State, March 14, 1911, as a technical coöperative society. The organization was accomplished without the fanfare of trumpets, voluminous press notices, and the trimmings which usually accompany the birth of a new organization, and the reason for this was that those having the matter in charge believed that the best way to enlist the support of the engineering profession was to go ahead and do something, leaving the fireworks to come afterward.

The organization was effected, by-laws adopted, officers were elected, committees appointed, and work started in less time than is usually required for the average committee to meet and adopt a set of resolutions. The society is now a living, vital factor in the world of mining and metallurgy. It is not an 'honor' society. It is a society composed of earnest conscientious men who find their livelihood in following the mining and metallurgical professions and who hope by banding together to accomplish good both for themselves and others similarly employed. It is hoped that the movement will be a broad one, and a cordial invitation is extended to all engineers, both in this country and abroad, to join the society and give it their loyal support.

It has been said that there are already enough societies of this kind in the country. I know of only one—the American Institute of Mining Engineers. The American Mining Congress, a most worthy institution, is organized on entirely different lines, and the Mining and Metallurgical Society of America has set such a high standard for membership that the average engineer is not eligible. It is admitted that the American Metallurgical Society is organized on much the same lines as the American Institute of Mining Engineers, but the character of our work will be entirely different from that of the Eastern society. The 'sphere of influence' of the Institute is east of the Rocky Mountains; that of the Society is in the West. An inspection of the transactions of the Institute will clearly show that, aside from the coal interests, that organization is out of touch with the country west of the Rockies. It is proposed to make the new society a purely Western organization. Not Western in the sense that its membership will be confined to the West, but Western insofar as the character of its work is concerned. Western methods, Western ideas in ore treatment, Western mines and minerals; those will be the subjects with which the society will concern itself. A society that will be truly representative of the West, such is the ambition of its founders. It is intended to go even further and to arouse among the members a spirit of coöperation which will find its expression in a desire to help one another, particularly in the matter of securing employment. The society will father this idea by appointing a committee to receive applications from disengaged members, and by advertising and other means will endeavor to procure appointments for them. It is believed that mining companies will heartily approve of the plan and will give it their earnest support. The need for some such plan of coöperation has been dwelt upon at length by a number of writers in the technical press during the past few months. I believe that the engineering profession will heartily approve of the efforts of the society in this direction.

Returning to the subject of supporting technical societies, I wish to draw attention to the tendency of engineers to ignore the small organization and to crowd into the Institute. This is not for the best interests of the profession. Competition is the life of trade, and it is also the life of an organization. The swollen membership roll of the American Institute of Mining Engineers is not conducive to the best interests of that organization. If the Institute had an active competitor, the friendly rivalry which would naturally spring up between the two organizations would result in a great deal of good accruing to the profession. The disbanding of the Western Association of Technical Chemists and Metallurgists is a case in point where a most worthy organization was permitted to go out of existence because of the tendency of engineers to confine their support to a single society. It is not so long ago but that man can recall the time when mining and metallurgy was not recognized as a profession. The 'mining expert,' now a picturesque memory of the past, was the representative of the craft. To what can be attributed the raising of mining and metallurgy to the dignity of a profession? For one thing, to the influence of technical societies. An organization of men for any purpose commands attention, and when that organization stands for high ideals, it commands respect not only for its members, but for the profession to which it stands as a living monument. But what of a profession which can support but a single prominent society? Is the layman likely to be impressed with the importance of such a profession? If there were a dozen active societies, would not our interests be still further advanced than they are today?

The American Metallurgical Society was organized after several months of careful thought had been given to the details of the organization and the financial problem carefully worked out. Headquarters have been secured in this city at 61 Fremont street, without cost to the society. While not large they are sufficient for our present needs. The publication of the transactions has been provided for in a way which will relieve the society of the burden of cost. This has enabled the society to make the entrance fee ($3) and the annual dues ($2) nominal. There is an additional charge of $1 per year for the transactions. In the case of the charter members who are now being admitted, the annual dues are remitted for the year 1911. For reasons already stated, the society was organized without the usual pyrotechnic display, and consequently there are many engineers who are unaware that such a society has actually been formed. Literature has been sent to those whose addresses are available, but there are many others with whom the secretary would like to get in touch. If there are any who, on reading this, would like further details regarding the society or would like to become identified with it, I would be pleased to forward to them literature and the necessary application blanks.

CARLOS P. GRIFFIN.

San Francisco, May 9.

[We are sorry the friends of the new society consider our comment unduly pessimistic, and we take pleasure in publishing this full statement of the plans of its organizers, by the secretary. With their ideals and purposes we are, as already stated, in full accord and we gladly wish them the best of good fortune.—EDITOR.]

Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

STAMPS are the most common crushing machines used in milling gold ore in California. At present there are 6033 in commission in the State.

CHROMITE is the only commercially important ore of chromium. It is a mixture of chromic oxide (Cr_2O_3) and ferrous oxide (FeO) in various proportions, the former averaging 40 and 60%, though occasionally running as low as 10, the latter running to 50%. The theoretical composition of chromite is $Cr_2O_3.FeO$ (Cr_2O_3 68%; FeO 32%). The price is based on 50% ore.

TO CLARIFY muddy water that does not become clear when allowed to stand, place some lumps of alum in a little tin shaker such as serve in kitchens for utilizing small pieces of soap, and stir the water with it for a minute or two. The water will quickly settle clear, and the amount of alum which is thus introduced has no deleterious effect even if the water is afterward used for cooking or drinking.

BAUXITE BRICK have been used in lining reverberatory copper furnaces and also in lining lead-refining furnaces. For this latter purpose they give satisfactory service, lasting much longer than silica brick, which are badly corroded by the basic oxides which rise to the surface as 'skims.' It is claimed that the lining of bauxite brick lasts five to six times as long as ordinary silica brick.

THE DEEPEST WELL in the United States, according to Isaiah Bowman of the U. S. Geological Survey, is near West Elizabeth, Pennsylvania. Its bottom is 5575 ft. beneath the surface. The deepest well in the world is in Germany and is 6572 ft. deep. A more remarkable well, perhaps, reaching a depth of 3600 ft. was drilled for petroleum in western China by primitive methods and by means of such crude appliances as a cable made of twisted strands of rattan.

TROY OUNCES contain 480 grains, while avoirdupois contain but 437½; since there are 12 troy ounces, but 16 avoirdupois ounces, per pound, there are 5760 grains (troy) per pound, or 7000 avoirdupois. The grain is the fundamental unit in both systems and was originally taken as the weight of a plump grain of wheat. To convert per cent of gold, therefore, to troy ounces per avoirdupois ton of 2000 lb., multiply by 29,176 and point off the appropriate decimal.

BLISTER COPPER which is too low in precious metals to make it worth while to attempt to recover them, and carrying impurities in too small quantities to be objectionable, is refined by the furnace process and cast into ingots. Such copper has too low conductivity to be used for electrical transmission purposes and is rather too impure to be desirable for brass making or rolling. Possessing certain desirable physical properties, however, it makes good copper castings, and is chiefly used for this purpose.

WET CONCENTRATES are hard to handle and many plans for drying them have been devised. At the North Star mine, Grass Valley, California, a sheet-steel side-dump concentrate car is used that is U-shaped in cross-section. This has been bored with numerous quarter-inch holes. Inside is placed a thickness of burlap, covered and held in place by coarse wire netting. Concentrate, after being loaded into this car, is allowed to stand and drain a few minutes before being trammed to the bin and dumped.

WATER is present to some extent in all rocks, but some formations, such as the granites, carry only an inappreciable amount. Sandstone, on the other hand, has an absorptive capacity of a gallon or more of water per cubic foot of rock and is the best water bearer of the solid rocks. Wells sunk in sandstone are usually drilled and the water derived from that rock is seldom polluted. To those who are contemplating sinking wells or increasing their water supply from underground sources, Water-Supply Papers 255 and 257 of the U. S. Geological Survey will be of especial interest.

CHURN-DRILL work must often be conducted when cold weather or steady rain interferes with the comfort of the men. In the Lake Superior region drills are often housed in, but where the drill is moved frequently this is expensive and difficult. At the El Oro dredge at Oroville, California, a housing has been devised that is portable. The sides and roof are made of frame covered with galvanized iron and built in sections. It is the work of but an hour or two to put the sections in place, and the time is more than made up because of the increased comfort of the men. Designs for such a structure must necessarily be made to fit each machine and varied somewhat according to conditions.

WIRE CABLES used in hoisting should be dressed with a mixture of 7 parts soft tallow and 3 parts of plumbago. A convenient way to apply this is to saw a 4 by 6 through diagonally, after having bored an axial hole a little larger than will take the rope, and make, by screwing four thin boards to the upper edge of the 4 by 6, a box large enough to hold several pounds of the dressing. This device is then clamped around the cable by means of a couple of bolts and secured in place by means of a scantling placed across the head-frame just below the sheave, and the cavity filled with the dressing and the cable run through. If old rope be shipped around the cable, it will catch on any broken strands and thus reveal defects. Standing wire rope which is exposed to the weather should be painted with a mixture of linseed oil and Spanish brown.

GOLD is commonly associated with arsenic, and especially with the mineral arsenopyrite. A remarkable association of native gold with native arsenic has been found in the Tokatea area, New Zealand. The arsenic forms hollow geodes with concentric shells that are easily broken off in succession. In the hollow interior are numerous interlacing dendritic threads of gold, which may in the aggregate weigh several ounces. The geodes often weigh several pounds and may be 6 to 8 in. diam. Gold is not found in the division planes separating the concentric spheres of growth. In the rich pay-shoots the gold is generally finely distributed throughout the quartz matrix. The minerals associated with the gold are native arsenic, stibnite, pyrite, chalcopyrite, and arsenopyrite. The frequency of association of arsenic minerals with gold would perhaps suggest that there must be some genetic relation involved, but the study of such deposits has not yet revealed the nature of such relations.

VANADIUM, which is used in the form of ferro-vanadium in making alloy steels, is obtained from carnotite (an impure vanadate of uranium occurring chiefly in Colorado) by agitating the crushed ore in a revolving barrel for one hour with a boiling solution of sodium carbonate. Both vanadium and uranium are extracted by this treatment. Sodium hydroxide precipitates the uranium as sodium uranate, which is filtered out. Slacked lime is then added to the filtrate, precipitating calcium vanadate, mixed with lime. There are several other processes in use. The vanadium assay presents little difficulty and does not require much time. The ore is fused with sodium carbonate, leached with water, and the fusion repeated on the residue. The combined filtrates are acidified with sulphuric acid, arsenic and molybdenum being precipitated in the hot solution by hydrogen sulphide, whereby the V_2O_5 is reduced to V_2O_4. After filtration and expulsion of hydrogen sulphide by boiling, the vanadium is titrated in hot solution by permanganate. It is then reduced by sulphur dioxide gas, and after boiling this out the titration is repeated. The results are exact, and they are not affected by the uranium that may be present.

Special Correspondence

NEW YORK

BRADEN COPPER.—GUARDED INTEREST IN PORCUPINE.—SELLING COBALT TO BUY PORCUPINES.—TONOPAH-BELMONT MEETING.—OKLAHOMA INVESTIGATION BUREAU.—KING PHILIP MERGER.—BLACK HILLS MINERAL PRODUCTION.

Robeson T. White, who built the plant of the Balaklala company in Shasta county, California, is to take charge of the construction work on the Braden. Pope Yeatman, now in Chile, is expected to return June 1. Evidently, from the requirements of this property, J. B. Haggin and his associates are not to own the only costly copper mine in South America. The Cerro de Pasco company in Peru has been requiring some vast sums to bring it to production, but Cerro de Pasco is not in the hands of the public, being rather a close corporation consisting of Mr. Haggin, the D. O. Mills estate, the H. McK. Twombly estate, J. P. Morgan, and some other associates. It is announced that the Braden Copper Co. will have to do some further financing. An additional bond issue of $2,000,000 is to be made, and the capital stock, now $12,000,000, is to be increased to $14,000,000 to provide for conversion privileges. Of the Braden's present authorized capital, $12,000,000, one-half is outstanding and one-half is in the treasury against the bonds of $6,000,000 already authorized and issued.

BLAST-FURNACE BUILDING, CERRE DE PASCO, PERU.

The general public is marking time so far as the new Canadian gold camp is concerned. The Eastern press is making a united stand against any and all publicity in behalf of Porcupine. The buyers of mining shares are almost invariably making scattering investments of hundred-share lots. The merits of the camp, beyond the two or three properties already demonstrated,' are unknown. It is clear that the East is ready for a mining boom, but Porcupine lacks the lodestone of high-grade ore to create the furore and excitement of a full-fledged mining boom. Just at this time, the Canadian trails are at their very worst, and development will be unimportant and news scarce until travel can be freely resumed. The Cobalt shares are almost wholly neglected, so far as market is concerned. The only activity in the Cobalt list during the past few weeks has been in the selling of shares to go into the new goldfield. Nothing could better illustrate the position of the lay mind toward mining exploitation as a whole. Cobalt shipments, just at the moment, are breaking records, but the fact that a wonderful 'poor man's camp' has made good in so large a way, and is making enormous returns on a comparatively insignificant investment, does not equal the anticipated glory of a new find. There is one feature of Porcupine's future, however, that is worthy of great consideration. If the field develops into a low-grade district with large orebodies, and an assurance of long life, the experience will do more to put mining on a high-class basis with the American public than all the booms of the various camps in the Rocky Mountains have ever done. If we can have a gold-mining district similar to the Rand, it will be an education for the American public, an education in the right direction, and away from pyrotechnics and questionable financing.

The directors of the Tonopah-Belmont held a meeting this week in Philadelphia. Plans are to be considered for a new mill of 450 tons daily capacity, which will be expected to eliminate smelter charges and effect some very large savings in other directions. Richard G. Parks, president of the company, resigned his office, owing to ill health, and is succeeded by Clyde G. Heller, former secretary of the company.

Speaking of questionable financing, it may be noted that Oklahoma is going a step farther than the projected law in Massachusetts. Oklahoma is proposing to establish a bureau for the investigation of corporations. Information is to be given to all inquirers concerning business enterprises, the principal idea being to protect investors against fakes. It is at least a hopeful sign that the way of the 'get-rich-quick' promoters is becoming a little harder to travel all the time.

The King Philip Copper Co. is to be absorbed by the Winona Copper Co. on a basis of two Winona for three shares of King Philip. Both of these Lake properties are practically close corporations. Copper Range is to absorb the Atlantic on a basis of ten Atlantic for one Copper Range.

One by one, the independent companies of Butte are losing their old identity. The Alice Gold & Silver Mining Co., one of the old companies of the camp and listed on the New York Stock Exchange, is about to give up its charter and be dissolved.

An echo of the old Harney Peak tin enterprise was heard this week in the application of the receiver for repayment of money paid to the United States Land Office. The Black Hills of South Dakota have produced several mining booms and one big mine. The various products sought have included copper, tin, gold, mica, porcelain clay, and marble. The richest 'hundred square miles on earth' is now sometimes spoken of as a country of samples.

TORONTO, CANADA

Rise in Rea Shares.—Prospecting the Timmins.—Find on the Jupiter.—Cyaniding Porcupine Ores.—Resumption of Normal Production at Cobalt.—McKinley-Darragh Dividend.—Blairton Iron.

The most noteworthy recent feature of Porcupine share dealings has been the demand for Rea shares, which yesterday touched $7.45 and will apparently contest the leading place with Hollinger. The cheaper issues have fluctuated considerably, but the general trend has been toward a higher level, though any marked advance is usually checked by a rush of profit-taking. At the Rea a station is being cut at the 200-ft. level, from which a cross-cut will be run to tap the vein. At 85 ft., before the vein left the shaft, average assays gave $65 per ton. Hand-drilling will be continued in the shafts put down by Bewick, Moreing & Co., Mr. Williams, who has charge of the work, stating that he finds it easier and cheaper to put down a shaft by hand until a good depth is reached, so that the compressor-plant will not be used for some time. On the three Timmins claims, east of Pearl lake, operated by Bewick, Moreing & Co., a camp known as camp No. 4 has been established for the accommodation of 75 men, with a six-drill compressor-plant and two hoists. Two drills will be used in prospecting. At camp No. 2, in North Tisdale, trenching and stripping are proceeding, to find quartz deposits that may indicate ore-

Eastern Canada.

bodies with depth. Sinking has just been started. The two shafts on the West Dome are down 46 and 75 ft. and diamond-drilling in several places has been done to the depth of 300 ft. On the Babyan claim, on the bed of Gillies lake bordering on the Hollinger, diamond-drilling has shown a 28-ft. vein. The Royal Porcupine, in which New York capitalists are interested, will begin operations as soon as possible on a location south of the Vipond, where three strong veins have been found. The Porcupine Imperial has a shaft down 80 ft., and when the 100-ft. level is reached cross-cutting will be started to pick up three veins showing on the surface. A good find was recently made on the Jupiter property, comprising the two Shillington claims north of Pearl lake, where free gold shows plentifully in a streak of quartz seven feet thick.

The question of whether Porcupine ore will require to be treated with cyanide is beginning to receive some attention, though hitherto it has been rather overlooked or relegated to the future, owing to the more pressing problem of proving large orebodies. The Hollinger and the Dome have arranged for the erection of cyanide plants in connection with their stamp-mills, but the general opinion of engineers is that the camp will furnish large quantities of free-milling ore, and that the introduction of cyaniding at this stage may be premature.

The increased shipments from Cobalt indicate that the difficulty arising from power shortage is being satisfactorily overcome. Many of the plants which were forced to close down or greatly restrict operations have resumed their normal production. The management of the La Rose is opening up a third level in the main shaft at a depth of 270 ft., the deepest point so far attained in the workings. A station has been cut, and driving is being done along the main vein. Developments on the second level of the Lawson mine show much improvement as compared with the first level, and this property now furnishes a large proportion of the high-grade shipments. The Crown Reserve has adopted a policy of deep mining. In the winze on the Carson vein, sunk from the 300-ft. level a depth of 150 ft., or a total of 450 ft. below the surface, has been reached. The Nipissing is also going deeper. A winze is being put down 75 ft. below the third level of shaft No. 64. The McKinley-Darragh has declared a quarterly dividend of 10%. This brings the total amount returned to shareholders to $1,706,000. The Silver Leaf property is being worked by the Crown Reserve. The shaft which is down to 420 ft. will be sunk lower so as to cut the Keewatin. Green-Meehan appears to be coming back. About 1000 ft. of driving has been done since A. W. Thomsen took charge and the ore extracted solely in the process of development has more than repaid the $30,000 expended. Charles A. O'Connell has been appointed manager of the Trethewey in place of George MacNaughton, who resigned to look after his interests in Porcupine.

The Blairton iron mines in Belmont township, Peterborough county, Ontario, have been sold by the Pearce company of Marmora, to the Blairton Iron Mines Co., Ltd., of Toronto, for $75,000. The latter company has had the property under option for three years, during which time its value has been thoroughly tested by diamond-drilling. The mine was operated many years ago, but the enterprise was abandoned on account of the expense of transportation. The company has also secured two large iron mines in North Hastings and will build a mill at Trenton.

ELY, NEVADA

Progress for Year of Nevada Con.—New Pits Opened.—Reorganization of Ely Central and Ely Centennial.—Good Progress in White Pine County.

The statement of the Nevada Consolidated Copper Co. for the quarter ended March 31, which has just been filed with the county assessor and tax collector, presents some very interesting figures. During the quarter 653,385 dry tons of ore from Copper pit were treated at the concentrating plant of the Steptoe Valley Mining & Smelting Co., an auxiliary company of the Nevada Consolidated. The gross yield of the ore was $2,296,036, which showed a net profit above transportation and treatment charges of $490,739, or 75c. per ton. Transportation charges amounted to $174,908, or 27c. per ton. The extraction amounted to $379,615, or at the rate of a little more than 58c. per ton. The reduction charges for the quarter amounted to $1,250,772, or a little less than $2 per ton. These figures are made on dry ore, while the cost of transportation is based on wet ore. The cost of transportation from the mines to the plant is 25c. per ton, which includes the moisture, while the treatment charges are for dry ore, which makes the cost run up to 27c. per ton. The loss in concentrate and smelting amounts to about 30%. The management experienced much trouble, which materially reduced its output, during the first quarter of the year, caused by the ore freezing in the cars and also by water shortage due to the cold weather, which affects the water-supply for about two months in the year. The output for the present quarter will probably be nearly 20% greater than that for last quarter. The physical condition of the property is most excellent. A daily production of about 10,000 tons is now maintained, which could be largely increased without much additional expense, if there was a demand for the ore at the plant. Seven sections of the concentrating plant are kept in constant service, while one section is usually down

undergoing repairs. The new Liberty pit, about a half-mile west of Copper pit, has produced some ore, but no effort is made in that direction at the present time. The ore produced is being taken out in development work. However, the new pit could be drawn upon for a considerable tonnage if desired.

The Ely Central company is about to be reorganized, with a treasury fund sufficient to thoroughly test the property. The committee on reorganization has been successful in raising the money to pay off all liabilities of the company, and as soon as the receiver has been dismissed and the property transferred to the new company, development work will again be undertaken. The Ely Centennial company has also recently been reorganized, and its stock made assessable, which will permit the company to raise money as needed for development work. The company's holdings lie immediately north of the town of Ely, near the eastern end of the mineral belt. The company has done more than 2000 ft. of development work during the past year and a half, which demonstrated a leached-iron zone 200 ft. in width. It is expected that a winze will be sunk in this vein to water-level, where the secondary enrichment should be found.

There is considerable activity in mining throughout the country at the present time. The eastern end of the county, especially, has taken on new life during the past year. The Amalgamated Nevada company has erected a 10-stamp mill for the treatment of its ores at Blackhorse, and will also treat custom ore, which will materially assist in livening the old gold camp. A plant is being erected at Sacramento pass, near Osceola, by the Ohana company, and will go into commission within a few weeks. Considerable tungsten ore is also being treated near Osceola, the concentrate from which has a value of about $500 per ton. The concentrate is shipped East for refining.

DENVER, COLORADO

NEW DESIGNS FOR ELECTRIC TRANSPORTATION.—LINE PROJECTED IN MONTEZUMA AND ARGENTINE DISTRICT.

An interesting and rather novel feature in electric transportation will be utilized by the Automatic Transportation Co. of Buffalo, N. Y., which has signed contracts with the mine owners of Montezuma and Argentine, to

AUTOMATIC TRANSPORTATION IN WINTER AT BLOSSBURG, PA.

transport their ore to the railroad, a distance of six to eight miles. It expects to begin in May the work of building its electric tram road, probably completing it by November 1, 1911. The new features are that the rails carry the power for the operation of the cars, and do away with the third rail, or overhead trolley, and can be operated with 220 or 440 volts, which is a low voltage, considering the distance; they use a direct-current motor, which means a low cost of operation for power. The cars are run in small units, each car carrying a motor, though operated by one motorman to a train. The construction of this line is also a new departure in mountain railroad building, and consists of a 4 or 6-in. post of common iron pipe, with a square base, set in concrete, 3 ft. deep by 18 in. square; the grade of the road is maintained by shortening or lengthening the poles as required; this saves excavation for a grade, which is an expensive item in the Rocky Mountains, and at the same time it leaves the rails 5 to 12 ft. above the ground, out of the snow, which falls to an average depth of 4 ft. in winter. The 30-lb. rails used are hollow, and made in the form of a fish-hook, being bolted to an insulated fastening, which rests on a malleable cross-arm weighing about 120 lb.; thus the whole railroad is constructed of iron and steel. A brush contact is made underneath the hollow part of the rail from the motor, so that neither ice nor sleet affects the operation of the road. On account of being able to operate on a 10 to 20% grade for short distances, the road can be built almost straight, so that a line can be run direct to a mine or mill which could not be reached by a railroad. It requires about 100 tons of steel and iron to the mile to build the road, the posts being set 10 ft. apart. The cars being 12 ft. long, no more than one car at a time can rest on one pole. These are capable of sustaining 63 tons, and as the cars carry only from one to three tons each, the maintenance of such a road will be very cheap. Another marked advantage is that the cars all dump automatically, and can be loaded the same way; the trains are operated at a speed of about 20 miles per hour, the passenger coach seats eight people comfortably, and can carry as many trailers as necessary; they are electric-lighted and heated. Flat cars to carry lumber and machinery are used as well as the automatic dumping ore cars. What this road means to the mines of Montezuma and Argentine districts can only be appreciated by one who has hauled over mountain roads twelve months in the year. The Montezuma and Argentine districts have the ore, but have been under great disadvantages, soft coal costing from $12 to $16 per ton, delivered at the mines, and the cost of hauling ore from the mines and mills to the railroad being from $3 to $5 per ton; but with the advent of the Summit County Power Co. in the district, which supplies electric power equal to the cost of steam-power with coal at $2 per ton, and the fact that the Colorado & Southern Railroad Co. has cut its freight rate from $3.25 to $1.75 per ton on ore to Leadville, with a promise of even a lower rate on low-grade ore in the near future, this district will be able to ship low-grade ore direct to the smelters at Salida and Leadville.

LONDON

CONCENTRATION BY FLOTATION.—DEMONSTRATION OF THE PROCESS AT NEW YORK.—COPPER CARBONATE MINES AT CHESHIRE.

I have so often written in your columns on the subject of concentration by flotation that I am particularly interested in the news that the Minerals Separation Company has established an office in New York under E. H. Nutter's charge with the object of giving American metallurgists a practical demonstration of the working of this process. I may say that Mr. Nutter is fully conversant with the intricacies of this principle, having been for over a year engaged in Australia and elsewhere in studying its application and getting to know all its details. It is highly desirable that Mr. Nutter should have had this opportunity for absorbing past experience, for flotation is one of the most ticklish problems within the domain of the mining engineer and metallurgist. The physical principles involved are obscure, and it is difficult to predict the results obtained on any individual ore. It is therefore essential that experimental work on its application to particular mines should be in the hands of an expert. Another point which I wish to press home is that American metallurgists should not be in too great a hurry to pass an opinion as to the efficiency of this method. Americans have a reputation for making quick decisions and of not having too much patience. A quick decision on the subject of flotation is to be deprecated. Also, the fact that many

ores will not be responsive to this treatment must not be used as an argument against its general value. The standing in law of the various owners of flotation process has been impunged recently by our distinguished contemporary in New York, which argues that the processes are free to anybody and that not a single patent could be substantiated. The two cases of anticipation quoted by the *Engineering and Mining Journal* do not give a lucid idea of the question as to the validity of the patents. To give one point only: Minerals Separation Co. relies on its discovery that only small proportions of thin oil are necessary when used in a certain specified way. It will be remembered that the MacArthur-Forrest cyanide patents were upset because the patentees did not expressly show that cyanidation was made a commercial success by their discovery that weak solutions had a special virtue. The Minerals Separation position seems to me analogous to this, and for that, if for no other reason, it is best for American metallurgists to make further enquiries before taking the *Journal* as guide.

A few weeks ago I recorded the attempts to re-open some of the old lead mines in the Carboniferous limestone in Derbyshire. Since then another similar project has been placed before the public, being a proposal to re-open the old carbonate of copper mines at Alderley, Cheshire, not far away. This ore is found in the Keuper sandstone of the Upper Trias, and some galena and cobalt compounds are associated with it. The deposits have been worked from time immemorial, and the extent of the workings shows that large amounts of ore must have been extracted. The proximity of the Lancashire chemical manufacturing districts makes acid cheap, and leaching processes are therefore applicable. My own recollection of the mine, judged by repeated visits twenty years ago, is that there is difficulty in obtaining a continuous supply of ore averaging more than 1% copper in any quantity; but the present sponsors quote a higher content, and are confident that they can make sulphate of copper at a profit. About £4000 cash has so far been subscribed, but this is not enough.

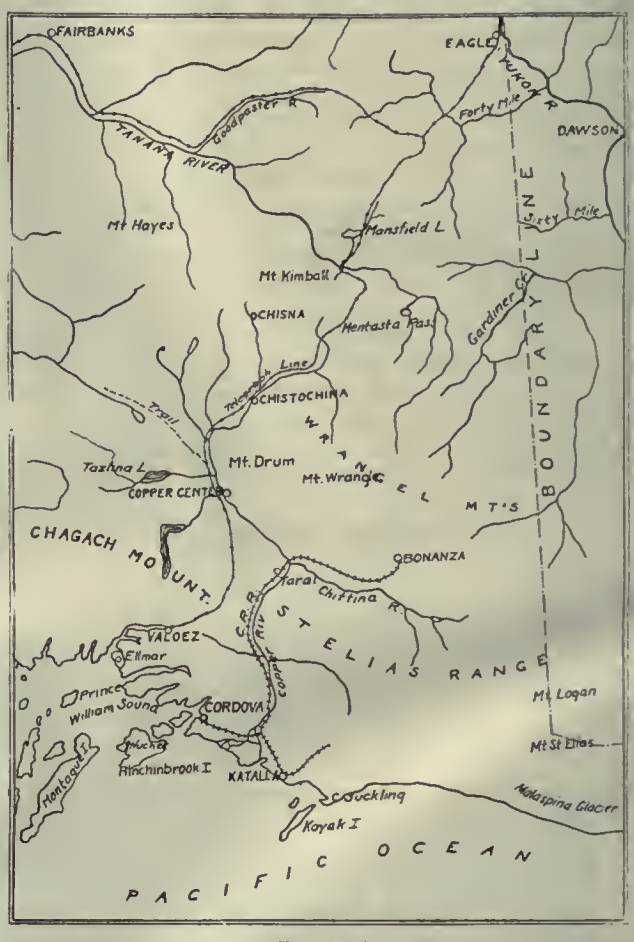
WASHINGTON, D. C.

THE CUNNINGHAM LAND CASES.—CLAIMS IN CHUGACH NATIONAL FOREST.—APPEAL OF THE STRACEY CASE.—MINING LEGISLATION.

Decision in the Cunningham coal-laud cases is expected in about two weeks. The attorney for the claimants has attempted to prove that there had been no thought of combination among the various entrymen prior to the time when their rights to their claims had been acknowledged by the Government's acceptance of the purchase price for the lands. Walter Fisher, Secretary of the Interior, sat with the board. The Secretary is putting much time and thought on the Alaska coal-land situation, and, seeing the necessity for an early adjustment of the difficulties, is bending every effort in that direction. The reply to the resolution calling for information as to the claims in the Chugach National Forest, in Alaska, shows that four locations, based on 'soldiers' additional homestead scrip' have been filed at Juneau by R. S. Ryan, promoter of the Controller Railway & Navigation Co., and three of them are now under consideration by the Land Office.

The Government has appealed the case of the Stracey group of claims to the United States Supreme Court. Judge Hanford of Seattle quashed the indictment against the men involved, on the ground that, under his interpretation of the coal-land laws applicable to Alaska, the indictment had not stated an offense. The appeal involves the indictments against Charles F. Munday, an attorney of Seattle, Washington; Archie W. Shiels, employed by Algernon Stracey, and Earl E. Siegley, formerly secretary to Michael J. Heney, who built the White Pass railroad and the Copper River railroad in Alaska. It does not include that against Algernon Stracey, who was indicted along with Munday, Shiels, and Siegley, but who was absent when the others were arraigned. It was from the alleged interest of Stracey and his brother, Sir Edward H. Stracey, an English baronet and Liberal member of Parliament, in the land, that the name 'Stracey group' or 'English group' was given to the claims. The Government charged in the indictment that Munday, Shiels, Siegley, and Algernon Stracey entered into a conspiracy to defraud the Government out of 6000 acres of coal land, valued at $10,000,000, just west of the so-called Cunningham coal-land claims.

Asle J. Gronna, the new Senator from North Dakota, has introduced three bills affecting the land laws. The first provides for the classification of the public lands of the United States; the second for the disposal of coal and coal lands; and the third seeks to authorize the disposal of phosphate, oil, asphaltum, or natural gas. Robert La Follette, Senator from Wisconsin, has introduced a bill providing for the valuation of the segregated coal and asphalt lands and the surplus lands in the Choctaw and Chickasaw nations, and of the surplus lands in the Creek nation, in the State of



COPPER RIVER, ALASKA.

Oklahoma; and for the sale of the surface and the disposition of the mineral rights therein. William H. Andrews, delegate from New Mexico, has introduced two mining bills, the first to authorize the exploration and purchase of mines within the boundaries of private land claims, and the second to authorize the Secretary of the Interior to sell and convey the unappropriated nonmineral desert lands of the United States. Richard W. Austin and M. D. Foster have introduced bills to appropriate from the sale of public lands $5000 for the first year, $10,000 for the second, $15,000 for the third, $20,000 for the fourth, and $25,000 for the fifth and each succeeding year, for the maintenance of a school or department of instruction in mines and mining in each State and Territory.

J. A. Holmes, director of the Bureau of Mines, has been chosen to represent the Government in settling the smelter-fume troubles at Anaconda, Montana. L. D. Ricketts will represent the company, and J. H. Hammond will arbitrate where necessary. Preliminary to considering the particular problems at Anaconda, Mr. Holmes will visit other plants throughout the country. F. G. Cottrell will act as one of his special advisers. Sumner S. Smith, of the Bureau, will assume his new duties as mine inspector in Alaska July 1.

General Mining News

ALASKA

Copper River

The Great Northern Development Co. the operations of which at Copper mountain, near Kotsina river, are in charge of E. F. Gray, formerly of Ely, Nevada, has kept a force of 40 men at work for the past year or more, and has a 600-ft. adit and 20 cross-cuts into the ore, which is reported to assay 12 to 17% copper, with some gold. It is claimed a branch is to be built to the property from the Copper River & Northwestern railroad.

Juneau District

The mill report of the Alaska Mexican for the month ended April 15, shows that 17,937 tons of ore was crushed, from which $44,685 was recovered, at a net profit of $11,980. Dividend No. 63 of 20c. per share has been declared by the company, and dividend No. 93, of 50c. per share, has been declared by the Alaska Treadwell. The board of directors of the latter has changed the fiscal year so that it will hereafter end May 31.

(Special Correspondence.)—The Alaska Treasure Gold M. Co., operating on Douglas island, is developing its property by means of two cross-cuts. The first to be driven was the Hudson cross-cut, whereby a body of ore was opened 200 ft. below the vein cropping; a winze was sunk on ore from this level. The main cross-cut, 750 ft. vertically below the Hudson, was driven 3400 ft. At 2600 ft. in from the portal a body of ore was found, and in driving on to the 3400-ft. point other orebodies were opened, the average values of which have not yet been determined. The work now in progress consists in driving from the face of the main cross-cut northerly to get immediately under the workings on the Hudson level. Development is to be continued during this year, and it is probable that a mill will be erected next season. T. A. Harper is superintendent; the consulting engineers are Pearse, Kingston & Browne, of London and New York.

Juneau, May 1.

Prince William Sound

The Cliff mine, situated in the vicinity of Valdez, is being operated by a leasing company, having a lease that runs two more years. It belongs to R. Ellis, to whom royalties amounting to $35,000 have been paid within the last eight months. The stockholders of the leasing company have received dividends aggregating $125,000 since the lease was given. A 6-ft. vein of rich ore was opened on the lowest level last month, and this is said to be a branch of the main vein, which is much narrower. The Valdez M. Co., having an active mine near Valdez glacier, 8 miles from town, has made good progress in development work during the past winter. The adit-level has been driven 200 ft. on the vein, showing the latter to have an average width of about 7 ft. This adit starts on a precipitous mountain slope, 1000 ft. higher than the surface of the glacier. The transportation of supplies to the mine is difficult, the road extending 1500 ft. up the face of the glacier, crossing crevasses over bridges. The top of the glacier is said to be level and smooth.

CALIFORNIA

Amador County

(Special Correspondence.)—It is stated that the run of the Bunker Hill mill at Amador for 26 days in April yielded gold valued at $27,000. Considerable low-grade ore was handled, this quartz being extracted in course of development on the 1950-ft. level. At this point an excellent body of ore is being opened, the quartz showing the same value as demonstrated at the 1750-ft. point. In the mill 40 stamps are in operation. E. H. Harrington is superintendent. It is reported that the famous old Plymouth Consolidated mines, at Plymouth, have passed into the hands of a strong company, and will be re-opened. A deed has been recorded, conveying the property to the Lane Investment Co., said to be composed of Eastern investors. The property was at one time one of the largest producers on the Mother Lode, and was opened to a depth of 1500 ft. At the time of its operation mining and milling costs were high, and the owners were forced to cease work because there was no profit. The mine has been idle for 20 years. The Kennedy, at Jackson, the premier producer of the Mother Lode, continues to maintain a heavy yield. The production amounts to $90,000 to $100,000 per month, much of the ore coming from the vicinity of the 3500-ft. level. The Kennedy enjoys the distinction of being the deepest gold mine in California, and has been the principal factor in proving the persistent nature of the Mother Lode veins. At the Argonaut preparations are being made for more vigorous development

and production. A number of districts throughout the country report increasing activity.

Jackson, May 13.

Nevada County

The Nevada County Deep Drainage & Development Co. has been reorganized, with W. H. Martin, F. J. Sloat, George W. Downey, C. E. Clinch, F. M. Miller, I. W. Hays, D. E. Morgan, and A. W. Hoge as directors. The object of the organization is to drive a drainage adit from near Jones bar, through the Nevada City district. It is estimated that the principal vein system of the district can be tapped at a distance of 15,000 ft. from the portal, and at depths ranging from 1050 ft. at the Champion mine to 1800 ft. at the Pittsburg. The plan contemplates the extension of the adit beyond this vein system to the Town Talk ridge, thence farther on into the Grass Valley district. The finding of new orebodies not exposed at the surface, it is believed, will be one of the advantages attained by driving this adit. The estimated cost of driving to the nearest producing mine is $175,000, and the income to be derived from drainage service, ore haulage, and water-supply, it is estimated, will exceed this sum per year. The directors have chosen as president, Fred M. Miller; vice-president, G. W. Downey; secretary, G. M. Noyes; treasurer, D. E. Morgan. Those who stand as sponsors for the project are interested in mining in Nevada City district.

Plumas County

(Special Correspondence.)—The Four Hills mine, near Johnsville, has resumed operations after a winter spent

in prospecting, and the owners, Hood and Breese, are getting their 20-stamp mill in good condition, 10 stamps of which will be operated this season. It is understood that the present force will be increased, and that the mill will be kept running on the average $6 ore which has been found in the recently discovered ore-shoot. It is reported that a second ore-shoot has been discovered, but the grade of this ore has not been determined. The Jamison mine, near Johnsville, is operating as usual on a good grade of ore, and it is said there is a sufficient quantity blocked out to keep the mill running for a year or more. The Plumas Eureka Mines Co., also operating at Johnsville, is employing about 50 men, the majority of whom are engaged in opening the old workings which were found in bad condition after some 15 years of idleness. The superintendent, D. J. Lawton, states that he intends to resume work in the intermediate levels of the old mine this summer, and that he will develop the mine on the lower or Eureka level, by a cross-cut following in the direction of the upper or Seventy-Six level. The Eureka is running 30 stamps, and it is believed that this additional development work will furnish sufficient ore to feed the 40 stamps with which the mill is equipped.

Johnsville, May 13.

Shasta County

(Special Correspondence.)—Developments at the Balaklala mines are proceeding with renewed vigor. The adit, which will eliminate the use of the aerial tramway by permitting the shipment of ore to the smelter from the mines by cars, is progressing at the rate of 200 ft. per month. Operations have been resumed at the company's siliceous gold-ore property in the Quartz Hill district, with a force of 100 men. The U. S. Dredging Co. expects to place its dredge in operation within a few days. The boat has been thoroughly overhauled and placed in good condition.

Redding, May 7.

In the annual report of the United States Smelting, Refining & Mining Co., Frederic Lyon discusses the bag-house system of collecting furnace fume, and has the following to say relative to the bag-house at the Kennett smelter: "The bag-house was put in operation July 5. It was a success from the very beginning and removed all the deleterious substances from the fumes, just as the bag-house was doing at Midvale. The success is the more gratifying, as this bag-house is the first erected in connection with a copper plant. There being no precedent to guide the engineering department in such problems as filtering area and cooling surface, it was considered wise to be conservative in the construction, so as to avoid an unnecessarily high expenditure of capital. As a result it was found, on completion, that the bag-house was not able to take care of the fumes of four furnaces, but did care successfully for the fumes of two furnaces. In order to comply fully with the decree of the court which permits the company to operate, and in order to live up to the spirit of the understanding with the farmers, it was considered wise to operate the smelter at one-half capacity, in spite of the increase of treatment costs per ton of ore and the material reduction of profits which were the necessary result. Experiments were at once started with a view to finding means to increase the capacity, and before the end of the year these experiments were so successful that a third furnace was started without any addition to the bag-house. By the installation of an auxiliary fan the company will be enabled to operate three furnaces steadily and successfully. The experiments will be continued with a view to further improvements."

Sierra County

Mining operations are more active than usual in Alleghany district. A 10-stamp mill is being built at the Tightner mine; the Sisson mill at the Red Star mine has been continuously operated during the past winter. The Croesus mine, in charge of C. W. McMeekin, has exeellent surface equipment, is developed by about 10,000 ft. of adit-levels, drifts, and cross-cuts; recent work consists in sinking a winze at a point 3000 ft. from the portal of the main adit, the purpose of which is to open at greater depth rich shoots of ore which were mined on the higher levels.

The North Star mine, at Pike City, which has been under development many years by G. A. Houreade, is reported to have been bonded and leased to J. P. Maleville, of Grass Valley, and others. The work performed during the winter resulted in opening ore that runs high in free gold and gold-bearing sulphides. It is said that 70 tons of this high-grade ore is ready for shipment. The Sierra Buttes mill is operating on high-grade ore. It is reported that a stamp-mill is to be built this season at the San Luis, near Sierra City.

The Nonpareil claim, near Alleghany, located two years ago by John Marthaler and Lee McCoy, who bonded it later to the Codd Mines Co. of Reno, has gold ore running $12 to $15 per ton. This was found in a 4-ft. vein on which a 450-ft. adit was driven last winter. The adit is being extended, and within the next 150 ft. the serpentine contact is expected to be reached, where high-grade ore was found on other properties. The adit will attain a depth of 350 ft. at the contact.

Tuolumne County

(Special Correspondence.)—Operations are soon to be resumed at the Omega, a small crew of men, under the direction of Joseph Loney, being already engaged in preparatory work. Some retimbering will be done. It is reported that an examination is to be made of the Porto Fino property mine for Oakland investors, who have in contemplation the bonding of the property. Work has been resumed at the Street mine, near Tuttletown. A gas-engine and pump are to be put in at Mandich mine, on Brown's Flat, the flow of water having increased to such an extent as to cause a temporary suspension of work. The mine is operated by Dan Mandich. Suit to recover $5550 has been brought in the Superior Court of this county against the Big Casino Mining Co., by W. M., S. M., and J. H. Witt, and D. C. Warren, who allege fraud in the sale of the several thousand shares of stock which they purchased in Texas from an agent of the company in 1906. The plaintiffs assert that it was represented to them that the company owned the mine, which is situated near Big Oak Flat; that there was no debt on the property, and that 20 stamps were in operation on ore ranging from $10 to $17.50 per ton, all of which allegations they declare were untrue.

Tuolumne, May 6.

COLORADO

Clear Creek County

(Special Correspondence.)—The Bard Creek M. Co. recently shipped 50 tons of ore from claims on Lincoln mountain, worth $50 per ton in gold, silver, and lead. The Clyde B., owned by James Beshears, has shipped 70 tons of ore, worth from $45 to $50 per ton in gold. Both the above-named properties are situated in the new gold camp of Clear Creek county. Work on a large scale is in progress at the Conqueror mine, on Covode, where a 100-ton concentrator will be built. George Schneider is manager.

Georgetown, May 15.

(Special Correspondence.)—A 6-in. streak of ore has been uncovered in the Little Mattie mine that shows ore running as high as 57 oz. gold and 140 oz. silver per ton. W. S. Leebrick is manager. A streak of ore 8 in. wide has been encountered in the drift being run on the West Lake mine that is worth 2 oz. gold per ton. There is also a 3-ft. body of mill ore that is worth $11 per ton in gold and silver. The New Era mine at Freeland is to be equipped with a mill having a daily capacity of 60 tons. James Cousins, of Freeland, is manager. The Denmark adit of the Consolidated Vindicator M. Co. is now in 820 ft. An ore-bearing vein has been intersected, believed to be the Tom Turk.

Idaho Springs, May 15.

Gilpin County

(Special Correspondence.)—The Anchor mine being operated by the North American S. & M. Co., has become a heavy producer. An average of 25 tons of smelting ore is being extracted daily that is worth $30 per ton. A shipment of 30 tons of ore from the Baker mine, operated by Semmens & Co., sampled $30 per ton. Operations are being carried on through the La Crosse adit, connection having been made with the shaft. The Rover mine has been taken under bond and lease by J. Pintarelli & Co. A gasoline hoist has been purchased, and now driving is in progress from the 220-ft. level. The shaft on the Chase mine has reached about 600-ft. depth, and it is to be completed at 700 ft. The shaft on the Pittsburg mine is now down 1000 ft., and, after providing a sump 20 ft. deep, driving will be started east and west.

Central City, May 13.

Lake County (Leadville)

The Siwatch adit, in Sugar Loaf hill, has reached a length of 3100 ft. and should cut the first known vein in 400 or 500 ft. more. A large flow of water has been met; this is taken to mean proximity to a vein. In the Dolomite shaft, in Adelaide park, the drifts are being driven steadily to the east and west. The Cryolite, on Fryer hill, is now shipping carbonate ore. The Ballard, on Breece hill, is working on a fair orebody, toward the south, and is shipping about 35 tons per day. A number of new enterprises have been started during the past month and several old ones have increased their scale of working. The receipts of ore at the Leadville smelters are heavy and the feeling is general that conditions are excellent.

The Little Johnny continues to produce very rich gold ore, many tons having been produced that run over $100 per ton. In the Star mine, on Carbonate hill, lessees have found a vein of silver ore running over 100 oz. per ton, while prospecting for zinc carbonate. The old Iron mine on Carbonate hill has showed some good bodies of zinc carbonate as a result of the prospecting which has been going on there. In the Chrysolite mine, under lease to Kirk White, a good body of zinc ore has been found, and regular shipments are being made, and a big body of ore has been blocked out.

Pitkin County

An event of much importance in Aspen is the unwatering of the Free Silver shaft of the Smuggler mine, which was allowed to fill with water fourteen years ago. Divers were sent down the shaft and succeeded in starting the pumps. A large area will be drained by this shaft and its influence on the whole district will be marked.

The San Juan

The annual meeting of the shareholders in the Frank Hough mine was held at Denver last week, and steps were taken toward the re-equipment of the buildings that were destroyed by fire recently. During this season the Revenue will do most of its work through the Ophir adit, but ore will be sent down to the mill on the Ouray side, and the concentrate will be shipped from Ouray. The Mono-Baltic M. & S. Co., which has been planning to erect a smelter at Ouray, has made a payment of $50,000 on the property. They have taken over the old Saratoga mill and 50 tons of machinery was hauled up last autumn. The proposed smelter is to have a capacity of 250 tons per day. The Primos Chem. Co., which operates vanadium mines at Newmire, has just received a new air-compressor and will soon have air-drills at work in its mine, where 100 men are employed. The disturbed conditions in Mexico have lessened the production of the properties owned there by the General Vanadium Co., so more dependence is being put on the Colorado mines. G. B. Pickett has obtained control of the old Suffolk properties at Ophir and is developing them. The mill has 20 stamps in running order, and twenty 650-lb. stamps are being replaced by 1050-lb. ones. Men are at work on several levels, but the mill has not been started yet. The Torpedo-Eclipse, which owns 16 claims in the Sneffels district, hopes to have its mill running within a couple of months. Ten men are now at work in the No. 4 adit, and work will be started soon in No. 1. The King mine, near Silverton, has started work. The Iowa-Tiger has found a new orebody on its fourth level. It is hoped that the litigation over the Peerless San Juan may be settled soon, so that work may be resumed. The mill at the Ledge Con., which is being enlarged and will start June 1, will have a capacity of 4000 tons per month.

Teller County (Cripple Creek)

The Favorite mine, on the southwestern slope of Bull hill, which was sold in 1900 to W. S. Stratton for $90,000 and which has long lain idle, has been leased to Howard Sholts, who has incorporated the Cripple Creek Mohawk Leasing Co. The surface equipment has been reconstructed and new machinery put in; the second shipment has been made, and machine-drills are now running on three levels. A rich ore-shoot has been found in the Flying Cloud mine, on the east slope of Bull hill, assays ranging from $16 to $100 having been obtained. The production for April of some of the important Cripple Creek mines is given in the following table:

Mines.	Tons.
Vindicator	3,400
El Paso	2,750
Isabella	1,350
Ajax	1,350
Findley & Shurtloff	675
Doctor-Jack Pot	450
Mary McKinney, main shaft	250

The annual meeting of the Doctor-Jack Pot M. Co. will be held June 14. The quarterly report of the president, A. E. Carlton, shows that 14 sets of lessees are at work, and the royalties paid by them during the last quarter amounted to $2561. Cash on hand amounts to $12,789. The decision of the U. S. Court of Appeals in the Work case has not yet been handed down.

IDAHO

Shoshone County

(Special Correspondence.)—During the last four months the Caledonia M. Co. has been shipping close to 700 tons of ore per month. Some shipments sampled 10 to 15% lead and 100 to 150 oz. silver per ton; others contained

Scene in the Coeur d'Alene.

about 39 to 45% lead and ran 60 to 80 oz. silver. Throughout the mine are lenses and small bodies of ore which are very rich in native silver. Charles McKinnis, the manager, states that the lower adit-level, which is to tap the vein at considerable depth below present workings, has been driven 1000 ft. During March, 333 ft. was driven by working two 8-hr. shifts. Eventually a concentrating mill will be built for the Caledonia, though no definite plans have been made for such a plant.

Kellogg, May 8.

(Special Correspondence.)—The National Copper M.

Co., having a group of claims three miles northeast of Mullan, is believed to have the extension of the Hecla vein. Some time ago a 400-ft. shaft was sunk on the vein, and some driving was done from the 200 and 400-ft. stations; but the excessive flow of water made it necessary to abandon work in the shaft. At the collar of the shaft a drift of 1200 ft. was driven on the vein, the ore being galena and silver. Later a cross-cut was started to open the vein far below the adit level. The heading is now in 1500 ft., and driving is in progress. The vein will be reached at 4500 ft. from the portal.

The Carbonate Hill group of claims, three miles from Mullan, is being developed by George H. Martin, D. K. McDonald, and others of Spokane. They have driven an adit about 1200 ft., by which 500-ft. depth is attained. George Houston, of Mullan, states that this group is on a belt of green chloritic quartzite, associated with several basic dikes; that ore occurs in coarsely-spaced lines of sheeting, cutting vertically through the bedding planes. This zone strikes east and west and is said to be traceable about 18,000 ft. Nearly 8000 ft. of development has been done on various properties of the belt, only a small part of which has been cross-cut work, by which these closely-spaced lines of sheeting are opened, and by which they are shown to be filled with siderite, iron pyrite, galena, and zincblende. Four veins have been intersected by cross-cutting; the lenses of ore in the veins are 2 to 8 in. wide. Some of the samples assayed 60% zinc, and showed a good grade of galena and silver. The Carbonate Hill people are to set up an air-compressor on the property and work with power-drills.

Mullan, May 8.

(Special Correspondence.)—The third vein in the Success mine was opened at 100 ft. above the highest cross-cut and 250 ft. below the surface. It has a width of 15 to 20 ft., and contains lead and zinc ore. The mill level, which is a cross-cut to the system of veins, is 450 ft. lower than the other cross-cut referred to. Between the highest and lowest levels a vast amount of ore is exposed. The entire output of the mine is concentrated, whereby lead and zinc concentrates are produced and shipped to seperate markets. The former product runs 55 to 60% lead and 40 oz. silver, the latter 45% zinc. Shipments amount to about one carload of concentrate per day. The mill is being increased in capacity by adding rolls, jigs, and tables. This property is owned by H. F. Samuels and associates.

Wallace, May 6.

(Special Correspondence.)—The Northern Light M. Co. is developing a vein of lead ore which occurs in quartzite and is situated on Pine creek, two miles west of Wardner. Open-cuts, two adits, and a shallow shaft are said to have shown a 5-ft. vein containing about 1 ft. of galena ore of high grade, and 4 ft. of ore of milling grade. Some samples assayed 70 to 80% lead, and 17 to 20 oz. silver per ton. Among those interested in the property are John H. Nordquist, Rush J. White, William J. Hall, B. N. Barnett, and Leroy Hooper, all of Wallace. A hoist and pump are to be put in and the shaft will be sunk 500 feet.

Wardner, May 10.

MONTANA

Deer Lodge County

(Special Correspondence.)—The activity started a few weeks ago in the Georgetown district still continues, and now nearly every claim is being worked, some with a good deal of success. The Venezuela, a property owned by local people, is the latest to make a discovery of rich ore, and this has caused an additional rush to the district. The roads are now in a fair condition and hauling of ore has been commenced to the Washoe smelter. According to reports from men who have recently visited the locality, the different properties have between 400,000 and 500,000 tons of ore ready for shipment. The revival in the district results in increasing the trade of the merchants of Anaconda. Georgetown is twelve miles from the smelter.

Anaconda, May 12.

Lewis and Clark County

(Special Correspondence.)—The first dredge ever put in operation on the Missouri river has been started up at Lake Sewell, at the mouth of Magpie gulch, twenty miles from Helena. The dredge was built by the Magpie Development Co. at a cost of $150,000, and has a capacity of 120,000 cu. yd. per month. The money for its construction and operation was put up by California and Seattle people. The company owns 400 acres of ground, which is sufficient to furnish work for six years. The dredge is operated by electricity and is being worked continuously with three crews of men. The manager of the company is O. W. Van der Grift, who formerly was in charge of the first dredge in Alder gulch.

Helena, May 12.

Silverbow County

(Special Correspondence.)—The latter part of July will witness the completion of the work of shaft-sinking at the Ophir mine of the Butte Central Copper Co., and W. L. Credon, the consulting engineer, is of the opinion that ore of a high grade will be found by driving. Mr. Credon says there is possibly sufficient silver ore blocked out on the upper levels to warrant the construction of a concentrator, but he is not going to advise the erection of such a plant until he can actually see that there is enough ore to pay for the concentrator at least three times.

R. M. Atwater, general manager for the Butte & Superior Copper Co., states that all the money from the sale of the bonds has been paid into the treasury, and as a result all of the company's outstanding indebtedness has been retired. He states the company's finances are now in a satisfactory condition, and that the problem of building a concentrator will be taken up in earnest. Shipments are at the rate of 400 tons of ore per day to the Basin plant, and the improvements and rearrangement of machinery there are showing satisfactory results. The recoveries since the middle of April have been better than at any time heretofore. The shipments of concentrate during April exceeded 3000 tons.

Butte, May 12.

NEVADA

Nye County

(Special Correspondence.)—A large interest in the Halifax-Tonopah Mining Co. was sold in Salt Lake last week by Thomas Kearns and David Keith of Salt Lake to F. M. Smith of California. The board has been reorganized as follows: President, F. M. Smith; vice-president, Thomas Kearns; treasurer, Christian B. Zabriskie; secretary, Frank J. Westcott; director and resident agent, Malcolm Macdonald. The property adjoins the Tonopah-Belmont on the east and comprises 81.31 acres of patented ground. Extensive development plans will be undertaken at once.

Tonopah, May 13.

The Mercury Mining Co. is developing a quicksilver mine at Ione, 50 miles south of Austin. A vein of fair-grade cinnabar ore is found in a rhyolite dike cutting through a limestone country. The property has been opened by means of a 700-ft. adit that connects with a 180-ft. shaft. A Scott furnace for distilling the quicksilver is being provided. Clifford Dennis is superintendent.

Storey County (Virginia City)

The board of directors of the Mexican Mining Co. has authorized Whitman Symmes, the superintendent, to have plans prepared for a concentrating mill and cyanide plant, to purchase the necessary equipment, and proceed with the construction. Work at the mine during the week ended May 13, is summarized as follows: (1) 2200-ft. level—The north drift from the northeast drift was extended 31 ft. and timbered; the face is in porphyry, with stringers of quartz, the rock sampling about $5 per ton, with a few cars running much higher. (2) 2300-ft. level—North drift No. 2 from east cross-cut was extended 14 ft.; there was mined from this drift 42 mine cars of ore averaging $18.03 per ton; the south drift No. 2 from east cross-cut was extended 12 ft., and from this 50 cars of ore averaged $64.61 per ton.

(3) 2400-ft. level—North drift from east cross-cut No. 2 was driven 31 ft., making a total length of 416 ft. There was taken from this drift 84 cars of ore of an average value of $46.77 per ton; the face is in a porphyry horse lying next to the hanging wall, and assays $9 per ton; a west cross-cut was started at end of north drift, toward the foot-wall; in driving 9 ft., 22 cars of ore was extracted, averaging $8.60 per ton. (4) 2500-ft. level—Work was continued in the raise in ore at end of north drift, which is partly connected with the 2400 north drift from east cross-cut No. 2; from this work there was mined 125 cars of ore averaging $112.83 per ton.

The Con.-Virginia work for the week ended May 12 was as follows: (1) 1465-ft. level—Jointly with Ophir S. & M. Co. the south drift, used as an air-way, has been under repair. (2) 1650-ft. level—At 100 ft. from mouth of the east cross-cut, that was started from the north drift 121 ft. from the centre of the raise, a north drift was advanced 24 ft. (3) 1750-ft. level—Worked on third and fourth floors and extracted 109 cars of ore averaging $12.54 per ton. (4) 1800-ft. level—Mined on third floor in stope and extracted 51 cars of ore of an average value of $4.91 per ton. (5) 2450-ft. level—South drift started from north line of mine was driven 2 ft., total length 282 ft.; face in porphyry, with seams of quartz; at 280 ft. from the mouth of this drift a cross-cut has been driven 11 ft. west. (6) 2550-ft. level—The southwest drift started from the north boundary of the mine has a total length of 100 ft., the face being in quartz, giving low assays; there was mined from the above openings during the week 160 cars of ore, averaging $9.77 per ton; shipped to Sutro mill, 154 tons of low-grade ore.

The Ophir mine operations for the week ended May 11 were as follows: (1) 2100-ft. level—The main northeast drift from west cross-cut was started at 200 ft. north from south boundary of mine, and work was performed on the third, fourth, fifth, sixth, seventh, eighth, ninth, and eleventh floors, from which was extracted 362 cars of ore averaging $39.34 per ton. (2) 2400-ft. level—In southwest drift, at 318 ft. in from its mouth, the west cross-cut was driven 12 ft., the face being in porphyry. (3) 2500-ft. level—The east cross-cut from the station cut out at bottom of the 3-compartment winze was driven 13 ft., total length, 107 feet.

OREGON

Josephine County

The smelter of the Almeda Con. Mines Co., at Galice, is reported in operation. The plant is equipped with a 36 by 72-in. water-jacketed, copper matting furnace that was designed and built under the direction of Frederic Powell of Portland. It has the capacity of 100 to 150 tons per day. One batch of ore from this mine showed as follows, by analysis: Gold, 0.1 oz.; silver, 2.3 oz.; copper, 2.8%; iron, 14.5%; sulphur, 20.9%; silica, 57%. Other samplings and analyses gave 16.5% barium, 26 iron, 28 sulphur, 3.5 copper, 22.9 silica. The property is managed by J. F. Wickham.

UTAH

Juab County

(Special Correspondence.)—The Lower Mammoth stockholders have voted to increase the capital stock from 250,000 shares to 1,000,000 shares. The increase will be distributed July 1 in the form of a stock dividend. Recent assessments have been on a basis of 5c. per share. The change has been made to produce a greater distribution of the stock, which it is believed will not seriously affect the price per share. Tintic district shipments for the week were 156 cars, Iron Blossom leading with 31, and Centennial-Eureka 27. Uncle Sam shipped six cars, including two from the recent discovery made by the Beck Tunnel Co. under their working agreement.

Eureka, May 15.

Salt Lake County

(Special Correspondence.)—J. G. Jacobs has revived his project of a railroad up Little Cottonwood canyon as far as Wasatch, which will greatly reduce the cost of bringing ore from the mines at Alta. He says he has ordered ties and will build the road this year. The Salt Lake Mining & Power Co., which has acquired the old Maxfield mine in Big Cottonwood canyon, announces that it will put in pumping machinery and unwater the mine.

Alta, May 13.

Utah County

(Special Correspondence.)—The Eudora Bell, in American Fork canyon, which was operated many years ago as the Silver Bell by the late Michael Shaughnessy, when it turned out high-grade silver ore near the surface, will soon again become a shipper. Between three and four cars of silver-lead ore, said to run from $75 to $100 per ton, is ready to go out as soon as the roads open.

American Fork, May 14.

CANADA

British Columbia

(Special Correspondence.) — The Mother Lode Sheep Creek M. Co., whose operations on Sheep creek are in charge of William Wilson, is to erect a small plant this season, to be equipped with stamps, a tube-mill, and cyaniding facilities. The machinery is to be operated by water-power. An aerial tramway, 4000 ft. in length, is to be erected to carry the ore from the No. 5 cross-cut to the mill.

Ymir, May 7.

Ontario (Cobalt and Porcupine)

Word has been received of the discovery of a fairly wide vein, running 124 oz. silver per ton, at Kipling, 30 miles from North Bay, 4½ miles from the railroad between that place and Sudbury. Some sixty claims have been located.

The trail to Porcupine broke up about May 1, and travel is now along the right of way of the railroad. The Brydge claim, adjoining the Preston East Dome, has been sold to New York and European interests for $350,000. The Hughes claims have been optioned to a French syndicate on the basis of $250,000 and 10% of the capital stock. It is hoped that regular trains will be running into Cobalt by June 15. The bridge over the Porcupine river is almost completed. The position of the terminus of the railroad has not yet been definitely fixed, and there is much speculation as to whether the line will eventually be carried to the Mattagami.

The shipments from Cobalt for the week ending April 29 amounted to 469 tons, La Rose and McKinley-Darragh leading with three cars each. The Crown Reserve, at Kerr Lake, sent 25 bars of silver bullion, weighing 23,128 oz., to England on May 2. A contract has just been made by this company with the Nova Scotia Cobalt at Peterson lake to mill the low-grade ore of the Crown Reserve. A wire-rope tramway will be built to transport the ore. The Coniagas paid dividends amounting to $350,000 on May 1.

MEXICO

Sinaloa

(Special Correspondence.)—The Jesus Maria Anexas mine, at San Jose de Gracia, out some distance from Casal station, has been closed down, and most of the American employees have fled from the country, on account of the prevalence of guerrilla warfare throughout the State of Sinaloa. Other mines have closed down, and many Americans are getting out of the country in anticipation of more serious conditions. It is reported that, especially at the smaller towns, and in mining camps, the *Insurrectos* are levying tribute on merchants and mining men. According to reports, the *Insurrecto* bands are vacillating and unstable, with no definite policy; also, that numerous instances are seen which demonstrate the disloyalty of the Federal troops. Roy Cohn, of San Francisco, who recently made his way out from the Jesus Maria mine, came to Culiacan, thence to Altata, from which place he went by boat to Mazatlan, where he took passage on another boat to Guaymas. This illustrates the difficulties of travel at present, as the railroads in Sinaloa are partly paralyzed.

Mazatlan, May 10.

Company Reports

INSPIRATION COPPER CO.

The first annual report of this company, covering the period from the beginning of work in February 1909 to January 1, 1911, shows that it has a capital of 1,000,000 shares, of a par value of $10, all of which have been issued. No ore has yet been produced on a working scale, as the mine is still in the development stage. The orebody consists of small seams, veinlets, and sometimes small grains of copper minerals disseminated through silicified schist. This occurs in a bed averaging 155 ft. thick, 3400 ft. long, and 1400 ft. wide (maximum), overlain by 367 ft. of leached capping. The ore has been developed by churn-drilling, the blocks being not over 200 ft. in length and no ore being allowed outside the lines connecting drill-holes. On this basis it is estimated that there are 17,173,000 tons of an average content of 2.02% copper, and 4,029,000 tons averaging 1.90% copper, an average of 543,000 tons per acre of surface. An experimental mill has been erected to furnish the data necessary for the construction of the 5000-ton mill which is planned. The Inspiration mine is at Globe, Arizona. The report of Henry Krumb, the consulting engineer, was reviewed in the *Mining and Scientific Press*, April 22.

THE CONSOLIDATED MINING & SMELTING CO. OF CANADA, LTD.

The fifth annual report of this company, operating mines and smelters in British Columbia, for the year ended June 30, 1910, shows that it has an authorized capital of 75,000 shares of a par value of $100 each, of which 55,552 have been issued. During the year 487,125 tons of ore was produced from the six mines owned or leased by the company (chiefly from the Centre Star, Richmond-Eureka, and St. Eugene) and was smelted at Trail, yielding:

Gold, oz.	137,614
Silver, oz.	2,162,406
Lead, lb.	42,368,816
Copper, lb.	5,974,959

Total value, $5,911,767.

The toal production from 1894 has been:

Gold, oz.	952,056
Silver, oz.	16,999,873
Lead, lb.	220,872,555
Copper, lb.	43,453,814

Total value, $42,646,025.

The receipts from the sale of smelter products and from rents was $6,721,468 for the year. The cost of mining, smelting, and general expense was $2,708,466; the freight cost was $200,950; the cost of development was $495,770; the cost of customs ore, lead, and bullion purchased was $1,666,504; royalties on ore, depreciation, directors' fees, and sundry claims amounted to $235,446; and $1,104,385 is charged to the ore and smelter products in course of treatment at the time of the last report, leaving a profit balance of $309,945. This added to the balance on hand at the beginning of the year gives a balance of $671,011. During the year the La Plata group near Nelson, and the No. 7 group in the Boundary district, have been purchased, and it is expected that these will prove a source of future profit.

NEVADA HILLS MINING CO.

The report of this company for the year ending March 31 shows that 182 tons of ore of an average gross value of $146 per ton was mined and shipped by the company, while 480 tons of an average gross value of $128 per ton was shipped by the lessees. The net return on the company's ore was $21,980, while the royalties received from lessees amounted to $13,178, a total of $35,160. The amount of development during the year was 11,184 ft., the larger portion of which was done on the Nevada Hills vein-system, although the Wingfield and Eagle veins were also developed. It is estimated that 21,500 tons of ore of an average value of $35 per ton is exposed in the mine, and an additional 5000 tons of $30 ore is on the dump. During the year the Fairview Eagle M. Co. was purchased by the Nevada Hills M. Co. on the basis of an exchange of one share of Nevada Hills stock for each six shares of Fairview Eagle stock, and for this purpose the authorized capital of the Nevada Hills M. Co. was increased to 1,250,000 shares of a par value of $5 each. During the year 100,000 shares were sold at 60c. each and 70,000 at 50c. each, making the total number now outstanding 1,061,645. During the latter part of 1910 plans were made for the construction of a 20-stamp mill, of an estimated capacity of 120 tons per day; this is now in course of construction and is expected to be ready for work by August 1911. A contract has been made with the Pacific Power Co. for electric power, and the transmission line should be completed during May. The Nevada Hills M. Co. has advanced $40,000 to the power company to be used in the construction of the transmission line, with the agreement that this sum, with interest at 6%, shall be repaid from the charges for power delivered to the Nevada Hills company. A description of the mill appeared in the *Mining and Scientific Press* for April 8. The property is as yet in the development stage, but gives good promise of becoming an important producer. It is near Fairview, Nevada.

LUCKY TIGER-COMBINATION G. M. CO.

This company, which owns the El Tigre Mining Co., S. A., has an authorized capital of 800,000 shares of a par value of $10 each, of which 715,000 are now outstanding. During the year the latter company milled 37,140 tons of ore and shipped to the El Paso smelter 2367 tons of concentrate and 1775 tons of picked ore. The average value of the ore mined was $36.57 per ton and was treated at the following cost per ton:

Mining	$ 2.468
Development	1.956
Tramming to mill	0.220
Ore-dressing	3.028
Freight on ore	1.134
Management	0.155
Ore expense	0.111
General costs	0.983
Total	$10.055
Less operating profit	1.222
Net cost	$ 8.833

The operating profit shown above was derived chiefly from the profits of the company store and the rent of dwelling-houses. The total profit from operations was $485,303, of which $429,000 was paid in dividends. The ore reserve now amounts to 218,280 tons, of which 67,780 tons is already broken in the stopes. The development to January 1 amounts to 40,708 ft., of which 5950 ft. was done during 1910, adding 27,340 tons to the reserve. As the company has paid 33 dividends, a total of $1,053,000, and is now paying regular monthly dividends at the rate of 5c. per share, it is reasonably clear that its financial position is excellent: there is little else in the financial report that is clear, and the manager's statement that the accounts are self-explanatory may be designated as too-sanguine optimism. If the accounts of the Lucky Tiger-Combination G. M. Co., which has a capital of $8,000,000, were clearly separated from those of the El Tigre M. Co., which has a capital of $15,000, much would be gained; and if the accounts and working costs of the latter were presented in such a way that they might be understood with a reasonable amount of effort, there would be no ground for complaint. The accounts of a small mine may be obscure and complex, for they are not a matter of general interest, and it may not be worth while to go to the expense of presenting them in an easily intelligible form, but a large and valuable mine which, like this, is the object of much general interest, might well set an example in presenting its report in an intelligible form.

Personal

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

C. S. Thomas, Jr., is in New York.

R. S. Schlessinger is in San Francisco.

Edward M. Rabu, Jr., is in San Francisco.

Stuart L. Rawlings is in San Francisco.

R. P. McLaughlin has been in San Francisco.

W. G. Swart, of Denver, is in San Francisco.

Whitman Symmes was in San Francisco this week.

H. F. Lefevre will be at Venezuela, Colombia, for two months.

G. H. Garrey has been in Washington, D. C., and is now in Illinois.

R. A. LeRoy will spend the summer at Spanish Ranch, California.

William A. Argall has left Columbia, Nevada, and gone back to Denver.

Charles W. Wright expects to spend some time in Switzerland this summer.

George Wingfield, of Goldfield, Nevada, is at the St. Francis hotel, San Francisco.

Henry C. Beeler has removed his offices to 1004 First National Bank building, Denver.

C. S. Herzig left New York May 5 for an extended trip to Peru, to examine a large concession.

Charles L. Constant, president of the C. L. Constant Co., has been in Cobalt on professional work.

G. S. Rice will go to Europe in June, to investigate mine-filling methods for the U. S. Bureau of Mines.

W. H. Emmons, C. W. Hayes, F. L. Ransome, and Arthur Keith have been at Ducktown, Tennessee.

E. R. Woakes left for Cape Town on May 6, to take temporary charge for the Cape Town Copper Company.

Urban H. Broughton has resigned from the Executive Committee of the Copper Producers' Association.

C. S. Burton & Co. have opened offices at 15 Broad street, New York, to carry on a general brokerage business.

J. B. Tyrrell is making an examination of the property of the Swastika Gold Mining Co., in northern Ontario.

Sumner S. Smith will be at the Pittsburg station of the U. S. Bureau of Mines through the first half of June.

Walter Bunce, who resigned the superintendency of the Sunnyside mine, at Eureka, Colorado, recently, is at Porcupine, Ontario.

John F. Wallace, former chief engineer of the Panama Canal, has become the president of Westinghouse, Church, Kerr & Co., of New York.

Theodore Dwight and Frank H. Probert are returning from Vera Cruz to New York. They have been at the Nueva Luz mine at Guanajuato.

Newton Cleaveland has retired from the active management of The Yuba Construction Co., owing to the pressure of other work in which he is engaged.

S. L. G. Knox is now vice-president and general manager for The Yuba Construction Co. He was formerly vice-president and general manager for The Bucyrus Company.

Lucien I. Blake, of the Blake Separator Co., has been married to Mrs. M. Beroset, of Trinidad, Colorado, and has gone to Europe on research work for the Submarine Signal Co. of Boston.

The Colorado School of Mines will hold its thirty-seventh annual commencement on May 26.

The Missouri School of Mines will hold its fortieth annual commencement on May 26. J. A. Holmes, Director of the Bureau of Mines, will deliver an address on 'The Individual, the State, and the Nation in the Development of our Mineral Resources.'

Book Reviews

Any of the books noticed in this column are for sale by, or can be procured from, the Mining and Scientific Press.

The Practice of Copper Smelting. By Edward Dyer Peters. 8vo. Pp. 693. Ill. McGraw-Hill Book Co., New York, 1911. Price $5. For sale by the *Mining and Scientific Press.*

This volume is written to replace 'Modern Copper Smelting,' by the same author, of which the first edition appeared in 1887 and the last extensive revision was in 1895, fifteen impressions having appeared to date. Meanwhile, the author's volume, 'Principles of Copper Smelting,' appeared in 1907, giving a complete theoretical discussion of the principles of the art. The present volume, therefore, is limited to a discussion of recent copper smelting practice. Since the publication of the first volume, Weed's 'Copper Mines of the World' has appeared, so that the volume under review properly differs somewhat in plan from its predecessor. The initial chapter on the ores of copper has been condensed to half the original space and entirely rewritten, since our notions of what constitutes an ore of copper have largely changed during the last two decades. The discussion of the distribution of the ores of copper is omitted. The chapter on sampling copper ore has been much expanded, while the discussion of assaying has properly been omitted. Only so much exposition of the principles of roasting is given as is required for the understanding of the discussion of roasting practice which follows. Blast-furnace smelting is likewise treated in two chapters, or 88 pages, rather than the four chapters, or 145 pages, in the former volume. Pyrite smelting is treated at double the former length and the discussion of reverberatory smelting, the bessemerizing of matte, and the refining of metallic copper, have been much expanded. The chapter on electrolytic refining has been omitted and new ones added on the treatment of fine ore and the dealing with flue-dust and smoke. With a brief discussion of slags and a chapter on furnace materials and construction, the heating of the blast, and the miscellaneous items of general information the volume concludes. An undeserved criticism is that too much space is devoted to smelting practice at Butte. When we remember that copper and lead smelting in America has almost entirely passed into the hands of large corporations of which many do not encourage the publication of details of technical practice by the engineers in the employ of the corporation, it is perhaps more remarkable that any papers of value on current metallurgical practice appear in the technical journals, rather than that they should be so few. Mr. Peters has therefore been largely restricted to papers in German and to French periodicals (where the larger number of important papers dealing with current metallurgical practice now appear) a few notable papers in English, and notes upon practice at plants managed by friends. It is discouraging to note that American smelting practice, which formerly was a model for the world of the free exchange of technical information, is gradually taking on the aspect of a 'close corporation.' Looking at it from this standpoint the book is quite the best presentation of copper smelting practice that can be expected, and all metallurgists will be most grateful for the gathering together in one volume of the widely-scattered information and the presentation of it in a form which permits the obtaining of an easy grasp. The 'public opinion' among students in the various mining schools has always been that 'Modern Copper Smelting' was the most readable text-book of metallurgy in print, and the present volume follows in the footsteps of its predecessor in this regard. Indeed, its faults are those of its virtue, and it may perhaps be questioned whether the treatment of copper smelting on page 24 as a purely mechanical operation in which the ore is merely melted down, allowing its constituents to separate into different layers according to their specific gravity, will not result in greater confusion of mind than a less general

statement would. Having classified copper ores into native copper, oxidized ores, and sulphide ores, it is strange that this method of classification was not extended to smelting, giving us the simple melting of the Lake Superior 'mineral,' the reducing smelting of oxidized ores, and the oxidizing treatment of sulphide ores. The technology of the smelting of Lake Superior 'mineral' is not profound, but it has much value in leading up to a clearer understanding of ordinary smelting, and the amount of copper produced in this way would alone justify brief discussion. The reducing smelting of oxidized ores to black copper is of little present importance, but a brief discussion of it would be of much value in throwing light on the oxidizing treatment of sulphide ores. For the reasons already discussed, the number of descriptions of plants now in operation is much smaller than is desirable, but the author has furnished new illustrations so far as they are available, a relief from the old diagrams taken from German texts that have been doing duty in America for the last twenty-five years. The book is printed on good paper, with a good index, and the typographical errors are not much more numerous than the employment of the linotype makes almost unavoidable. Such obvious errors as 'coneing,' which is repeated several times on pages 5 and 6, 'sulphides' and 'limestones' on page 91, 'E' in place of 'K' on page 151, 'unturned' for 'upturned' on page 450, to cite only a few, might have been eliminated by more careful proof-reading, and doubtless will be in the second impression, which may reasonably be expected to be soon required. The thanks of the metallurgical profession is due to Mr. Peters for this most welcome and valuable addition to his unofficial series of monographs on metallurgy. T. T. R.

The Reid Smelting System

A new and interesting electric furnace is being placed on the market by REID, LTD., with office in the Pennsylvania building, Philadelphia, Pennsylvania, and a complete testing plant in Newark, New Jersey. This furnace is the invention of J. H. Reid, who spent about six years in its development. While the furnace is essentially the same in design for all classes of ore, certain features are varied in accordance with the character of the ore itself. A descriptive catalogue is being distributed by the company. Some of the many advantageous features claimed for this furnace are as follows: Fusion is unusually quick, taking place within ten seconds after current is applied. The furnace can be started and stopped instantly at will, with no previous preparation and without reference to the charge or withdrawal of the same. Recovery of the metal content in both low and high-grade ores is practically complete, it being demonstrated by analysis of the various slags that they show about 0.1% of metal. It is estimated that the heat attained by the Reid electric furnace is over 6000°F. This is a much higher temperature than can be obtained in a blast-furnace. The manufacturers claim that the extremely high heat results in the production of a metal of great purity and avoids necessity for more than one refining, it then being within a small fraction of 100% pure. No preliminary treatment except crushing is considered necessary. Ore is taken from the mine, crushed, and fed to the furnace. No fluxes of any kind are used. Furnace linings are unnecessary, as in the Reid furnace the charge does not come in contact with the walls. By an ingenious arrangement the fumes and vapor from the ore are drawn off as they form and passed to condensers where by-products are recovered. The furnace is automatic in operation and control. The electric current is regulated within any required limit. Thus the heat intensity and volume are governed as desired. It is claimed that this electric furnace will be of particular advantage for treating small outputs, as the furnace itself can be supplied in small sizes. It is the intention of Reid, Ltd., to license users of the furnaces, royalties being based on tonnage treated. The operating expense will depend entirely upon the cost of the electric current.

TABLE OF CONTENTS

EDITORIAL

WATER sufficient to supply San Francisco for nearly three years is to be stored back of the great Calaveras dam recently begun by the Spring Valley Water Company.

EXAMINATION and certification of men trained for mine-rescue work, with a view to their temporary employment in emergencies, has been undertaken by the United States Bureau of Mines.

A SPECIAL committee of the American Institute of Mining Engineers, consisting of Charles F. Rand, Arthur L. Walker, Joseph W. Richards, E. G. Spilsbury, and Karl Eilers, has been appointed to study the question of organizing local sections of the Institute.

LOCAL meetings of the American Mining Congress have been held at Portland on May 16, 17, and 18, and at Seattle on May 20; the meeting at Portland being for the purpose of organizing an Oregon chapter of the parent Society.

SALTING is believed to be responsible for a loss of $75,000 sustained by Sacramento investors in the Bonnie Brier Mining Company; another example of the advisability of having a thorough investigation by competent engineers before investing.

HEROIC treatment was recently given to the new building of the E. I. du Pont de Nemours Powder Company in Baltimore, when, to demonstrate to the underwriters the fireproof character of the building, a fire was kindled within it, the doors closed, and the building left to burn if it would.

MYSTERY deep and dark shrouds the expedition that sailed from San Francisco on the schooner *Eureka,* early in May, for Central America. "Investigation of mining properties in Honduras" hardly necessitates chartering a ship, and there is a suspicion abroad that the motive for the expedition lies rather in the lure of buried treasure or the glint of filibusters' gold.

DISCOVERY of oil at Carlyle, Illinois, has increased the respect in which oil-men have held the work of the State Geological Survey. Leases were taken and wells drilled on the strength of the structure as shown in Bulletin 16, and a new field brought in. Mr. F. W. DeWolf, Mr. R. S. Blatchley, and their associates, are to be congratulated on this quick proof of their good work.

AS a result of an agreement between the Western Union and Anglo-American cable companies, the rate upon non-code messages which may be subjected to a delay of twenty-four hours or less has been reduced to one-half that formerly charged. This step toward the final taking-over of the latter company by the former, is a welcome addition to the increased facilities afforded by the use of 'day letters.'

ASSIGNMENT of rooms in the Customs House and Appraisers Building in San Francisco to the Bureau of Mines is taken as a welcome illustration that the metal mines of the West are hereafter to receive some attention from that Bureau. The excellent work already undertaken in the coalfields has the general endorsement of mining men, but there is a widespread feeling that metal mining problems should also be investigated.

EXCELLENT work is done at the Eagle-Shawmut mine in Tuolumne county by the Edwards furnace, where it is used in roasting a sulphide concentrate preliminary to concentration. The ore is roasted to ½% S with a consumption of 18 gallons of fuel-oil per ton and repair costs of but ½c. per ton. The furnace has a working capacity of seven tons, and when all the work is done on it the total cost is approximately $1 per ton.

THE controversy between German and American potash interests has been settled, and according to the new agreement the Americans will draw their total supply from the German syndicate during the five and one-half years which the arrangement is to last, at prices fixed by the German potash regulations. Unless the difficulties with the Schmidtmann group of firms are settled, the syndicate will take upon itself the solution of the remaining questions.

GRAFTING would soon become dangerous as well as difficult if company officials would all follow the example of Mr. S. P. Eastman of the Spring Valley Water Company. Being approached by an assessor with a proposal to reduce the annual taxes of the company $50,000 in return for a bribe of $25,000, Mr. Eastman laid a trap that resulted in the official being arrested with the marked bills in his possession. It is thus made clear that in the case of the larger corporations at least, a determined officer can protect his stockholders and the public too, if he really wishes to do so.

MUCH is heard nowadays of 'dollar diplomacy,' and while this excites little admiration as an ideal standard of foreign relations, yet it has its value in indicating that intelligent effort is now being applied to the securing of wider markets for American products. An excellent example of this is seen in the recent action of the Department of State in extending to the Commercial Bureau Company permission to supply each consulate with a filing cabinet filled with cards giving brief abstracts of the catalogues of American manufacturers, printed in the appropriate foreign language. Consulates have heretofore kept files of catalogues in an unsystematic fashion, but these were of comparatively little service to the foreign enquirer. The systematic and complete service thus afforded should result in much good; and it is noteworthy that the increased facilities are secured at no cost to the Government.

VOLATILIZATION of gold at high temperatures is a well known fact, but there is a tendency to exaggerate its importance. In the roasting of gold precipitates and telluride ores even the mechanical losses may be kept very low by careful conduct of the operation. This is emphasized by the results cited by Mr. J. W. Hutchinson in the part of his description of the operation of the Goldfield Consolidated mill which we print this week. In smelting the briquetted precipitate from the refinery in a small blast-furnace, it was found that the loss in the flue-dust amounted to one-eighth of one per cent of the precious metals, practically all of which was afterward recovered. The fine material caught by filtering the escaping gases through bags had a value of only $20 per ton, while the ordinary flue-dust had a value of $2500 per ton. The recovery is therefore complete from a commercial standpoint. In roasting Cripple Creek ores the usual loss in the flue-dust is one per cent, most of which is afterward recovered.

LIGNITE was discussed in an address before the American Philosophical Society, May 5, by Mr. J. A. Holmes. As is well known the Western and Southern States contain immense quantities of this low-grade fuel. The outlook for its utilization lies in further development of the gas-producer, in design of special boilers and fire-boxes, and in briquetting. In the first two lines rapid progress is being made. The excellent work of Mr. Lewis Skinner at the Western Chemical Company's works at Denver has done much to popularize the use of lignite in producers. At the Bureau of Mines testing station at Pittsburg, Mr. Holmes says that California, North Dakota, and Texas lignites have been briquetted by pressure alone. This elimination of an artificial binder marks an important step in advance, and with other improvements under way largely increases the value of lignite deposits.

COLORADO members of the American Mining Congress are to be congratulated on the results of their legislative campaign. Among other things endorsed by them and passed by the legislature were bills providing for a new system of mine taxation, coöperative mine drainage, facilitating punishment of ore-thieves, increasing the appropriation for the State Geological Survey, and an appropriation for completion of the testing-plant at the State School of Mines. Smelting and sampling companies were also made public-utility corporations. There is sharp difference of opinion as to whether this will prove to be a good or a bad move, and probably experience alone will settle the matter. The main fight of the session, so far as mining men were concerned, was over mine taxation. In the bill finally adopted three principles were established: (1) if mines are to be assessed on production the net and not the gross return should be taken as the basis; (2) non-producing property should be assessed much lower than is now the case locally; (3) mine improvements should be assessed in accordance with some simple and easily applied rule that will give the actual value of such improvements. The bill embodying these is now before the Governor for signature. Mine taxation involves many intricate problems, but certainly the surface ground should be taxed only on the basis of its value for the uses to which it is applied, and apparently the most just form of taxation that can be applied to ore is some form of production tax. Ore is comparable rather to a crop of timber or grain than to money stored in banks or cotton in warehouses.

Association of State Geologists

The annual meeting of the Association of State Geologists, and the attendant conferences with officers of the United States Geological Survey, the Bureau of Mines, and the Bureau of Soils, has come to be an event of general importance. Not only do these meetings promote acquaintance and forestall friction, but they are occasions for important exchanges of information as to methods. The officers of geological surveys have many problems of administration such as are not discussed in textbooks or school-room lectures, and the experience of one is appropriately available for all. At the recent meeting in Washington the conference with the Director of the United States Geological Survey was concerned mainly with allotment of funds for coöperative work, but time was found for discussion of the duties of surveys in the matter of educating people to use survey results, and the conditions under which

official prospecting should be undertaken. The session of the Association itself was devoted to discussion of methods of filing and indexing data, of making exhibits, and similar routine matters. Broader questions of policy came up in the effort to determine how far a Survey may wisely depart from the field of geology, and to what extent it should advertise. Engineers who have kept informed as to the work of Geological Surveys as they have developed in the United States, recognize that their scope has broadened until in most States the Survey has become practically a bureau for scientific investigation of mineral resources and for promoting their development. In the latter phase of their work Surveys in the United States have not used the accepted channels of publicity as have similar organizations in Canada, Australia, and elsewhere. If it is a good thing to advertise the resources of a State, it is certainly proper to do it as effectively as possible. While, owing to limitations as to funds, the State Surveys have not always been able to command the highest talent, they are doing a truly enormous amount of good work and their resources are neither sufficiently known nor utilized by mining engineers. We hope the Association will effect a change in this among other particulars.

Peace in Mexico

Peace has been proclaimed in Mexico, with the understanding that President Diaz and Vice-President Corral shall resign, and Señor de la Barra, who becomes president *ad interim,* will proceed at once to restore railroad and telegraphic service and to indemnify the losses incurred by non-combatants during the insurrection. But a phase of the situation that is of the gravest import is forcibly emphasized by the slaughter of 200 inoffensive Chinese at Torreon by the rebel troops. The telegraphic reports indicate clearly that the rebel leaders were unable to hold their men under control, so that they ran amuck like savages. To declare peace is easier than to secure peace, and unless there is a strong and steady hand in control it is likely that conditions in Mexico during the next few months will not be so tranquil as the best interests of all demand. The 'rebel army' is far from being a unit, the obedience which the scattered commands show to any central authority is but shadowy, and their pacification is likely to prove a slow task. Certain high-minded journals have deplored as sordid the argument that the commercial interests of foreigners in Mexico are of too great importance to permit an indefinite prolongation of disturbed conditions. This is wide of the truth; the damage to foreign investments is but an index of the vastly greater damage to the domestic interests of the Mexican republic. General Sherman is reported to have said "War is hell." It is not only that, but it is also foolish. To involve a country in domestic war to settle political questions, except of vital importance, is a proceeding on a par in intelligence with the setting on fire of a house in order to rid it of rats. The United States and Great Britain have agreed by treaty not to war with each other, even on questions involving national honor, and it is likely that the United States will make similar agreements with France and Germany. When questions of national honor can be settled by arbitration, political questions should be settled by less destructive methods than those of warfare. That there has been an insurrection is a blot upon the fair name of Mexico; its persistence will be a national disgrace. A firm hand is needed to grasp the tiller of the Ship of State. Señor Francesco I. Madero has shown that he possesses many high qualities, but he is confronted by a most difficult task, and the future must show whether he is the strong leader needed to meet the demands of the hour.

Chlorination Versus Cyanidation

The announcement that the chlorination plant of the Portland Gold Mining Company at Colorado Springs is to be converted into a cyanide plant, is an interesting and significant event in the protracted controversy as to whether chlorination or cyanidation is better adapted to the treatment of telluride ores; and must be a source of gratification to Mr. Philip Argall, who has so repeatedly urged the superior advantages of the cyanide process in the treatment of these ores. The Colorado City plant of the United States Reduction & Refining Company is now the only one using the chlorination process to treat Cripple Creek ores; and, indeed, the only large and important plant in the United States which is now using this process. It is reasonable to expect that at no distant date this also will be so converted as to employ only the cyanide process, which the same company has long been using in the treatment of tailing. But to infer from these changes that the employment of the chlorination process in the beginning was ill-advised, is not justified by a careful consideration of the conditions existing at the time when the plants were built. The cyanide process of 1911 is better suited to such ores than chlorination; but the cyanide process of that earlier date was not. Since the discovery of Cripple Creek radical and sweeping improvements have been made in cyanidation, while the chlorination process has been but little changed. The former has advanced with rapid strides, the latter has done little more than mark time, and has now dropped to the rear. The manufacture of caustic soda as a by-product did not prove so profitable an adjunct as was once hoped; and, except in the largest plants, the making of a by-product is generally likely to prove more a source of annoyance than profit. A plant where the efforts of all concerned are concentrated on doing one thing as well as possible, will in the end prove most successful, as well as most simple. The use of chlorine as solvent for gold, agitating the ore in horizontal rotating barrels, was first successfully practised at the Haile gold mine in North Carolina, when the southern Appalachian goldfields were still of great importance. It afterward was applied in Colorado, California, and Montana, and its good record permits it to honorably retire.

It is a curious fact that, despite the modern free interchange of information, practice at two such similar districts as Cripple Creek and Kalgoorlie, has developed with so large a degree of independence. The American metallurgists have been ready, however, to utilize the best features that have been developed in Australian practice; the Edwards furnace, for example. The use of bromo-cyanide, which met with approval in Australia at first, but now is falling out of favor, has been frowned on in Cripple Creek, an early attempt to use bromine having failed completely. However, its more recent application at the Goldfield Consolidated mill may in time lead to a successful utilization of the vigorous oxidizing power of bromo-cyanide. That reagent has so far exhibited the faults of its virtues and its vigorous oxidation has led to so high an operating cost that its use was unprofitable. The resulting situation was similar to that of the eminent surgeon, whose operation was completely successful though the patient unfortunately died. The steady decrease in the grade of the ore has brought Cripple Creek metallurgists face to face with a vital problem. The splendid work of the Golden Cycle mill is an excellent example of the way the present situation is being met, but the pressing need of the immediate future is to treat the low-grade ores, without roasting, at the mines. Important work has been and is being done by the Portland and other companies to solve this problem, and we may confidently continue to look to Cripple Creek for marked advance in the art of cyanidation.

Operation of the Goldfield Consolidated Mill

By J. W. Hutchinson

(Continued from page 686.)

Precipitation

The solution from the Butters filter is clarified in three 36 by 36-in. 60-frame Perrin presses, which are fed by one 4-in. Morris centrifugal pump, direct-connected to a motor. They have the capacity to clarify 2000 tons of filtered solution per day, equivalent to 1300 lb. of solution per square foot of filter-surface. To this operation must be accredited part of the success obtained here with zinc-dust precipitation. At times it has been necessary to pass part of the solution to the precipitation-tanks without clarification, and each time it has resulted in a precipitated solution of high metal content. The high-grade solution from the concentrate plant is clarified in a similar press and precipitated in the mill presses. The solution from the clarifying-presses gravitates to three 28 by 8-ft. redwood tanks, two of which are for the mill and one for the concentrate-plant solution. The usual Merrill equipment is used for feeding and emulsifying the zinc-dust, which gravitates through 1-in. rubber hose to the suction pipes of two 7 by 9-in. Aldrich pumps, which deliver the solution and zinc-dust to four 30-frame, 48-in. triangular Merrill precipitation-presses. These presses have 1680 sq. ft. of filter-surface and 140 cu. ft. of storage for precipitate, equivalent here to 1.6 tons solution per square foot of filter per day, and to ¼ cu. ft. of storage per pound of daily precipitate. Each press, when filled at a pressure not exceeding 5 lb. per square inch, will hold approximately 2500 lb. of precipitate containing 30% H_2O.

In figuring precipitating equipment for silver ores, the filter-surface is not the only consideration, as can be seen from the following instance. In evolving a process for treating a high-grade silver-gold ore, it was decided to precipitate 600 tons of solution from 120 tons of ore. The equipment, which a zinc-dust process company agreed to furnish, contained 384 sq. ft. of filter-surface, which would have been satisfactory for filtering. The storage-room in this equipment amounted to 32 cu. ft. The amount of daily precipitate at this plant is estimated at 400 lb. It can readily be seen that had this equipment been put in it would have been necessary to clean the presses every fifth day. It was finally decided to put in 800 sq. ft. of filter-surface and 70 cu. ft. of storage, and clean up three times per month. It seems that it would be advisable for the patentees of precipitating-presses to design a special press for silver ores with a greater proportion of storage room to filter-surface than the standard press in use has. It has been found necessary here not to allow the pressure to exceed 5 lb. per square inch; at a higher pressure the precipitate has a tendency to cake, which prevents the inflowing solution from filtering through the excess zinc-dust and being precipitated. This experience is in direct contradiction to the theory that precipitation is complete in the pipe-line, but it has not been possible here to corroborate this. After cleaning the presses, in order to insure satisfactory precipitation, it is necessary to use $^3/_5$ lb. of zinc dust with the first 250 tons pumped through the presses. After the filter-cloths have been coated with this excess zinc, the amount used varies from ⅛ to $^1/_3$ lb. per ton of solution. During the first 18 months operation the plant was supplied with most inferior zinc dust, which resulted in a high consumption of this chemical, as can be seen by referring to the subjoined table. In the latter part of 1910 it was decided to have this commodity shipped in metal-lined cases, similar to the cyanide package. The beneficial effect was immediate, and although the first cost is ¼c. per pound higher than the quotations for barrel packages, the consumption of zinc dust is reduced enough to offset this expense many times.

At the beginning of operations the strong and weak solutions were precipitated in separate presses. During this time the total zinc in the precipitate averaged over 30%. It was decided later to pump the strong solution, which titrates 4.5 lb. KCN and averages 1½ oz. gold per ton, through the weak-solution presses. By doing this the zinc has been reduced to 15%, and no more zinc dust is required to precipitate the 1½-oz. solution than is used on the mill-solution. This is one reason why it is believed here that the condition of the press is more important for efficient precipitation than length of pipe-line. Since the metal-lined zinc-dust package has been used, three presses are kept in constant operation, and the fourth cut-in only at the beginning of the bi-weekly clean-up. The clean-up car, which is steam-jacketed, runs on rails underneath the presses, as shown in the sketch. This change was made in order to avoid handling or transferring the precipitate, and is very satisfactory. Six hours are required for two men to clean a press and have it ready for operation. The work of cleaning is done by the refinery crew, which consists of three shifts of two men each. All filter-cloths for the clarifying and precipitating-presses are cut by the filter operators who have some little time during each cycle for this work. A double thickness of twill is used for filtering; when the outside cloth becomes worn, it is taken off, burned, and added to the precipitate.

The efficiency of this method of precipitation is shown in the following table:

	1911.	1910.	1909.
Value of Mill Solution—	Oz. Au.	Oz. Au.	Oz. Au.
Before precipitation	0.200	0.200	0.230
After precipitation	0.003	0.004	0.005
Percentage of recovery	98.5	98.0	97.8
Value of Concentrate Plant Solution—			
Before precipitation	1.56	1.22	1.40
After precipitation	0.014	0.016	0.017
Percentage of recovery	99.0	98.7	98.8

In the cost of precipitating is included the power required to elevate the solution to the press-room and the total cost of operating the clarifying-presses. The latter may seem unjust to the zinc-dust precipitation, but since it is a detail absolutely essential to the successful operation of this method, it should be charged against it. The solution from the filters, although apparently clear, contains a minute amount of flocculent slime which would cause the pressure in the precipitating-presses to rise if it were allowed to pass to them. In addition, the unclarified solution would precipitate, from a physical standpoint, on zinc-shaving, and as stated, it is thought here this cost is properly charged against the precipitation. The following table shows the cost, including cleaning-up and items mentioned above:

	1911.	1910.	1909.
Tonnage	850	850	600
	Cents.	Cents.	Cents.
Labor	1.0	0.9	1.3
Supplies	4.9	8.7	9.0
Power	1.4	1.4	1.7
Total	7.3	11.0	12.0

In spite of the fact that the heat was so intense it warped 12-in. I-beams, destroyed part of the steel structure of the press building, and burned the zinc in the presses, they passed through the refinery fire without damage, yielded 11,000 oz. of gold which they contained, without loss, and were in operation four days after the disaster.

Melting

The melting-room, as originally designed, contained a double-muffle drying-furnace and four Faber du Faur tilting furnaces for treating this precipitate. Apparently not enough experimental work was done on this part of the treatment while engaged in making the design for the

plant. The process as outlined consisted of nitre roasting the precipitate, with subsequent melting in the tilting furnaces. The bullion from this method averaged about 250 fine in gold and silver. The analysis given will explain why. Later, acid-treating tanks were put in, which materially reduced the amount of precipitate to be melted, and by the addition of pyritic concentrate to the flux, enough copper and lead were converted to matte to raise the grade of the bullion to 425 fine, gold and silver. The following is a typical analysis of the bullion originally made at the plant:

	Per cent.
Au	34.87
Ag	5.75
Cu	40.50
Pb	12.95
Zn	3.48
Cd	1.31
Fe	0.18
Mn	Trace
As	0.10
Sb	0.15
Bi	0.07
Ni	0.16
Co	0.03
Te	0.39
S	0.10

The process was unsatisfactory from every standpoint, as the comparative tables below will show. The fire, which originated in this melting-room, through the failure of a defective bushing in the fuel-line, made it imperative to go ahead with work which had long been planned but postponed on account of other work which seemed more necessary. Much work was done with a view of finding some wet method which could be economically applied to the precipitate. The large amount of base metals made the cost of reagents prohibitive. Electrolytic parting of the base bullion would have made it necessary to carry a large stock of silver in order to secure the correct proportion of silver to gold for rapid parting. This idea was abandoned on account of the high cost. Cupellation of the briquetted precipitate, as practised at the Homestake, was impossible on account of the high percentage of copper. Laboratory work with a modification of the Tavener process, in which enough sulphur obtained from concentrate was added to matte the copper, yielded a clean lead bullion, and low-grade slag and matte. The cupellation of this base bullion left a gold bullion carrying approximately 850 parts gold and 80 parts silver.

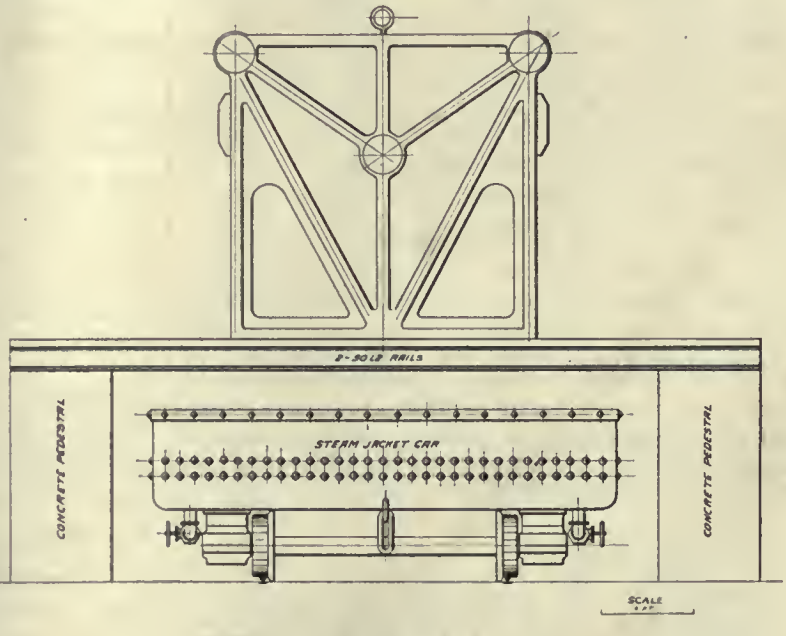
About the time it had been decided to briquette the precipitate with litharge and concentrate and smelt in a small reverberatory with suitable flux, Henry Hansen, the mill superintendent of the Pittsburg Silver Peak Co., at Blair, Nevada, told me of some experiments which he had been making with a small blast-furnace for smelting his briquetted precipitate. The refining process at that mill was at that time similar to Homestake practice. He had found the smelting of the briquetted material in the cupels a tedious operation, and had made some tests in a small blast-furnace which he was using for cleaning his cupel slags and for other clean-up work. The bullion from this furnace was cupelled, and the total time and expense of melting were reduced materially.

Smelting precipitate containing 40% copper on a lead basis did not sound very attractive as blast-furnace work at first, but after experimenting here it was decided it could be done very efficiently and economically. The precipitate is now treated in the following manner: The upper floor of the refinery is connected with the precipitating-room by a 30-in. gauge track with branches to each of the four presses. The steam-jacketed clean-up car is run underneath the press to be cleaned, the precipitate is dropped into it and hoisted to the refinery, where the total weight is determined on platform scales. After deducting the weight of the car and the moisture, fluxes are added in the following proportion:

	Parts.
Dry precipitate	100
Litharge	100 to 125
Blanket concentrate (S 35%, SiO_2 30%)	60 to 70

Flue-dust and floor sweepings in quantities to reduce the moisture to approximately 9 per cent.

The admixture of precipitate and fluxes in the car passes to a hydraulic elevator which delivers it at the feed-hopper of a two-mould Boyd press. This press was purchased from the Selby Smelting & Lead Co. and has a rated capacity of 30 tons in 24 hours. The dies have been changed to make a circular brick 4½ in. diam. and 3 in. thick, since the rectangular one was too large and unwieldy for use. Two men have no difficulty in fluxing and briquetting 2000 lb. of precipitate in 8 hours. One man feeds the press and the other receives the briquettes on rectangular trays, which are stacked in jacketed drying-carts and allowed to dry for 48 hours. Steam was used for drying during the winter when the heating plant was in operation. Having an excess of air, it was decided to heat it in one of the muffles of the drying-furnace, and allow the heated air to circulate through the trays of briquettes. This arrangement is very satisfactory and is more economical than the use of steam jackets.



MERRILL PRESS AND CLEAN-UP CAR.

The coke-bin is situated on this floor of the refinery and the coke can be shoveled to the furnaces with no extra handling. The blast-furnaces are of the cylindrical type, 20 inches in diameter at the tuyere line with riveted steel jackets, and provided with a removable curb, mounted on wheels. The jackets are arranged to be suspended from 15-in. I-beams which pass through the concrete retaining-wall. A Connersville blower direct-connected to a 10-hp. motor supplies a blast of 3 oz. per square inch for both blast-furnaces and the double English cupelling-furnace. This blower has a capacity of 10 cu. ft. of air per revolution and is operated at present at 250 r.p.m. Arrangements are being made to reduce the speed, as the supply is in excess of the amount required. The gases from all furnaces pass to a dust-chamber which contains 2700 cu. ft. There are nine take-out hoppers inside the building through which the flue-dust is drawn after each melt. The product recovered from the flue never exceeds 400 lb., and contains less than $500 in gold from a total value in the melt of

$400,000. In order to prove beyond question that gold was not escaping, an 8-in. Sturtevant exhaust fan was connected to the vertical stack and the gases filtered through muslin bags. The dust and fume collected from two separate tests of an hour's duration amounted in both cases to less than 5 lb., and assayed 1 oz. per ton.

The following analysis will give an idea of the baseness of the precipitate to be smelted:

	1911. Per cent.	1910. Per cent.	1909. Per cent.
Au	21.50	8.75	13.43
Ag	3.00	1.14	2.13

The furnaces are 'blown-in' in the following manner: A wood fire is built in the crucible, the blast turned on, and wood thrown in from the charging floor until the crucible and lead-well are cherry red. A few charges of coke are added and the blast maintained until the whole charge is white-hot. The blast is then cut off and about 500 lb. of pig lead fed in to fill the crucible. The siphon is kept plugged with brasque in order to fill the crucible and float the ashes, charcoal, etc., which are raked out and subsequently returned to the furnace. When these have been removed the siphon is opened and blank charges of coke and slag are fed until the furnace is half full. This operation requires about 2 hours. By filling the furnace with these blank charges a bed is made for the first charge of briquettes, which prevents dusting. When the furnaces are ready, the following charge is fed:

	Lb.
Briquettes	160
Old slag	40
Borax	10
Cupel bottoms	10
Iron (oxidized)	5
Coke	25

With the exception of one run, when the slag contained 15% Zn, and became too pasty to work well, 24 hours is required to smelt 16,000 lb. of briquettes. The lead bullion contains approximately 20% gold and silver and 1% copper, which makes the lead-wells 'mushy.' In order to keep them open it is necessary to pass a hot iron rod through the siphon. The matte-fall is about one-third of the weight of the briquettes and is collected in a portable settler, from which the slag overflows into pots. The matte from the precipitate-run contains approximately 20% Pb, 50 oz. Au, and 200 oz. Ag per ton. This is stored until a sufficient quantity is on hand to make a separate run. The crucible of one furnace is then filled with brasque, and the furnace operated as a copper furnace. The separation of lead and matte is made in the portable settler. This operation reduces the lead in the matte to 10% and the gold to 3 oz. By roasting this product and leaching the copper and silver with H_2SO_4 it has been found possible to avoid shipping it, and a small plant will soon be erected for this purpose. When the slag becomes too 'zincy' for further use, it is either discarded or shipped to the smelter, according to the value.

The composition of the slag is as follows:

	Per cent.
Insoluble	24.8
FeO	26.3
CaO	5.5
ZnO	12.3
Pb	6.5
Cu	1.3
Soluble silicates and borates undetermined: gold, 1.2 oz. per ton.	

Cupellation of the lead bullion is accomplished in a double English cupelling-furnace having removable tests, 3½ by 2½ ft. and 7 in. deep. The cupels are made of three parts cement and one part limestone; the latter is crushed to pass 6 mesh and the fine screened through 20 mesh and discarded. They are seasoned for six weeks before using and last for one run, cupelling approximately 4000 lb. lead bullion, after which they are broken up and fed to the blast-furnace with the next precipitate run. Thirty hours is required to cupel 8000 lb. lead bullion, during which time 25 barrels of oil is consumed. The litharge is caught in small ladles and examined for beads of bullion before it is sent to the grinding-room. Should any appear it is returned to the cupels. In finishing the cupellation it is necessary to add about 200 lb. of pig lead to each cupel in order to remove the remaining base. After the last matte and litharge have been floated off, the heat is raised and the blast increased for 20 min. to oxidize the film of base which cannot be removed mechanically. When oxidation is complete, the gold bullion is granulated by pouring into metal tubs filled with water. The material is then dried and melted with nitre and borax in a No. 60 Steele-Harvey tilting furnace. The bars thus produced, averaging 930 gold and silver, are shipped to the Selby Smelting & Lead Co. for further refining. Approximately 5% of the total lead used is lost. The matte and slag account for the greater part of this and the cupellation losses for the rest. The litharge recovered from the cupels is broken in a 4 by 6-in. Dodge crusher and pulverized to 20 mesh in a set of 7 by

PLAN AND CROSS-SECTION OF REFINERY, GOLDFIELD CONSOLIDATED.

14-in. rolls and used for fluxing the precipitate from the next clean-up.

The cut above shows the refinery in plan and cross-section. In order to make it the more easily understood, the names of the more important features have been placed on the drawing, and it will therefore not be necessary to give any further description. The building is a steel frame covered with wire netting and portland cement plaster. Concrete was used liberally in constructing floors and foundations, and it is as nearly fireproof as such a building may be made.

It is not intended to give the impression that the process is perfect, and that the usual amount of 'grief' has not been passed through in getting started; but when the character of the product is taken into consideration, the results are very satisfactory, as can be seen from the accompanying tables:

COST OF MELTING

	9.5	18.3	20.3

(To be continued.)

Travel and Mining in Honduras

By Rensselaer H. Toll

Situation and Extent

*Honduras has an area of but 50,000 square miles, less than half the size of the State of Colorado. Its population is estimated at 400,000; comprising 185,000 Indians, 205,000 of mixed blood, 5000 negroes, and 5000 whites, most of whom are of Spanish descent, though a great many Americans and Europeans are scattered along the coasts, in the larger cities of the interior, and through the mining regions. The coast-lines of Honduras run nearly east and west. The Caribbean coast is about 400 miles long and has many good harbors, such as Trujillo, Ceiba, Tela, Omoa, and Cortez, the last-named being the usual port of entry for travelers. The Pacific coast is occupied by San Salvador, leaving but sixty miles to Honduras, which, however, contains the beautiful harbor of Amapala. Both coasts are unhealthy, but the miasmic influence does not extend far inland.

As elsewhere in America, the principal rivers flow to the Atlantic. The Segovia, or Coco river, which is the boundary between Honduras and Nicaragua, is about 350 miles in length; but it flows rapidly over a shallow rocky bed and is navigable only by canoes. The largest river entirely within the boundaries of the country is the Ulua, which flows north and is formed by the confluence of the Santiago and the Comayagua, with their tributaries, the Santa Barbara and the Sulaco. Steamers of shallow draft can ascend the Ulua as far as the mouth of the Santiago, about 70 miles by the stream. The Comayagua river rises in the mountains at the southern border of the great plain of Comayagua, more than two-thirds of the distance to the Pacific coast; and the streams of the Ulua system drain about one-third of the entire territory of Honduras.

As a whole, the country is very mountainous, not even the coasts being free from rugged heights, for along the Caribbean many mountains raise their proud heads above the clouds while their feet are bathed by the ocean surf. Nor are their elevations insignificant, for many peaks reach an altitude of 9000 ft., while in the Sulaque mountains are some which approximate 10,000 ft. above the sea. Mountainous as the country is, there are no consecutive ranges of great length, the longest being the Sierra Madre, and this splits into two parts soon after leaving Guatemala. Between the various small ranges of mountains are broad fertile plains like that of Comayagua, which is about 40 miles long from north to south and 10 miles in average width; the plains of Yoro and Olancho, celebrated for the excellence of their cattle; the plains of Omoa, Sensenti, and many others, all extremely picturesque and fertile.

Mineral Resources

Honduras ranks high in mineral resources: among the metals so far discovered being gold, silver, copper, iron, lead, zinc, antimony, and nickel. Kaolin, opal, aluminum, chalk, coal, asphalt, and petroleum also are found in quantities which will doubtless render them all profitable under more advantageous conditions. All kinds of building stones, including marble of a fine quality suitable for statuary, are found. Because of the inadequate transportation facilities and civil strife, only the precious metals can be mined profitably at present. Many of the rivers, especially those flowing into the Atlantic, contain gold in quantities large enough for the Indians to work, and there are several small quartz-mines in operation. Some of the placer gold is said to contain platinum in so appreciable an amount as to be paid for by the United States mints. But despite this showing, the only mine of present importance in Honduras is the San Juancita, owned by the New York & Honduras Rosaria Mining Co., with headquarters in New York. This mine is in the department of Tegucigalpa, about 20 miles north of the capital, on the northern slope of a steep and high mountain formed principally of andesite overlying black shale.

The main veins, the Rosaria and Candelaria, strike generally east and west, dipping steeply to the north, in places being quite vertical. These veins have been worked for over thirty years, and there are about 30 miles of workings, with a vertical extent of 1800 ft.; but the mine is said to be in better condition now than ever before. Within recent years important north and south veins have been developed, which appear to have given the property a new lease of life. The mine is equipped with electric haulage, and a single-rope tramway conveys the ore to the mill, an old affair of fifty stamps and two tube-mills. The metals are extracted in the cyanide plant, which has mechanical agitation-vats and Butters filters. The precipitate is shipped to New Jersey, as the cost is about the same as for that of reduction at the mill.

About 3000 tons per month is milled, and the annual production is close to 1,000,000 oz. of silver and 16,000 to 17,000 oz. gold. About 2000 men are employed, of whom 40 are Americans. The equipment of the Rosario is constantly undergoing renewal and improvement, two very fine hydro-electric plants having been built recently; and a new mill and cyanide-plant, offices, hotel, and club-house are in course of construction on the mountain-side at the level of the lower adit, 1500 ft. above the present townsite. The property is connected with Tegucigalpa by a most outrageous cart-road, which in the higher mountains is very muddy because of the numerous springs; and the grade in many places is over 30%. As an illustration of the difficulties of operation in such a locality, it may be mentioned that the cost for transportation of heavy freight from San Lorenzo, the port near Amapala, to San Juancita is 5c. gold per pound, light freight costing about half as much.

Mining Laws

The mining laws of Honduras are very liberal. Any amount of ground may be denounced, but the usual size of claim is 500 hectares, or 1220 acres. By following a procedure similar to our patent proceedings, a title may be secured which is equivalent to a patent in the United States. The annual tax is 50cv. (about 20c. gold) per hectare, and so long as the taxes are paid the title remains absolute. But should they be unpaid for a period of two years, the ground reverts to the public domain and is open to denouncement again. As in Mexico, there are no extralateral rights, all boundary lines being vertical. For a small consideration one may obtain a concession to prospect and locate claims over a large area, during the term of which no one else is permitted to make denouncements within the specified territory. Upon application to the President, mining machinery and supplies may be brought into the country free of duty.

Ports and Railways

The interior of Honduras may be reached through Puerto Cortez on the north coast, and Amapala on the south coast. From New Orleans the United Fruit Co. operates small steamers which make the trip to Cortez in a little more than five days, stopping at Belize, British Honduras, and Barrios, Guatemala. The steamship fare is $27 one way. From San Francisco to Amapala requires 22 days and costs four times as much; hence, though the trip from Amapala requires but three days over a good road, and that from the railroad at Pimienta to the Capital requires six days over a bad trail, much time and money are saved by going through Cortez. If the traveler has time and inclination he may take one of the large new steamers of the United Fruit Co. and catch one of the smaller ones at Barrios. These larger vessels are of 5000 tons burden and very comfortable—almost luxurious—and a trip on one of them is quite a delight. During the wait at Barrios he may run up to Guatemala City, the metropolis of Central America, and spend a day or two viewing this interesting old city and laying in a supply of silver jewelry and silk shawls for souvenirs.

Cortez harbor is one of the best on the Gulf. It is ellip-

*Address delivered before the Colorado Scientific Society, April 1, 1911.

tical in shape, about nine miles in circumference, and deep enough for the largest vessels to anchor. Puerto Cortez is a straggling, crudely-built town stretching along the shore for two miles. Its single street is occupied principally by the Honduras railroad, whose terminus is the wharf at the lower end of town. At the upper end this road enters the jungle, bound for La Pimienta, on the Ulua river, 56 miles away, a distance usually covered by the train in about eight hours. This little narrow-gauge road is the first section of a transcontinental line which was projected to San Lorenzo, through the valleys of the Comayagua and the Goascoran, which practically bisect Honduras, a total distance of 232 miles. From 1867 to 1870 bonds to the value of about $30,000,000 were floated in London and Paris for the purpose of building this railroad. An English company took the construction contract on a percentage basis, and it was profitable, therefore, to make the construction as costly as possible. So, between the commission for the sale of the bonds and the padded accounts for material and labor, by the time the road had reached San Pedro the proceeds from $25,000,000 worth of bonds had been consumed; a cost of nearly $700,000 per mile. The road was finally completed to the Ulua river and graded several miles beyond, but the Government was bankrupt. Notwithstanding the enormous cost, the construction of this railroad was wretched. For miles the rails were laid upon the bare ground, without ties of any kind, being held in place by stakes driven in the earth. They soon became imbedded to such a depth that lateral movement was impossible, so the trains probably kept the track as well as they do now. But, bad as the track and cars are, this little railroad presents many interesting features. For many miles it runs through a dense jungle of palms and other tropical foliage whose sweeping branches cast grateful shade over passing trains, while the trailing vines, covered with morning-glories and flowers of strange shape and gorgeous colors, lend fragrance and magnificence to the scenery, which the most carefully cultivated lawns and flower-beds of our great Eastern roads cannot equal. A dozen miles from the coast the jungle frequently gives way to large cleared pastures, and *fincas* where the luscious banana hangs from the broad-leafed stalk; and at each station cars are being loaded with this nutritious fruit.

The day before our arrival at Cortez the American and upon the town and railroad, and the camp was in general readiness, if not eagerness, to cut down ruthlessly any revolutionists that might get off our train. Fortunately for us, we carried no such passengers.

Travel in the Interior

At La Pimienta one is obliged to take passage on a mule, and here the really tiresome portion of the journey begins, for five or six days on a Honduras mule is not the most delightful experience in the world, even to a stranger, to whom the wonderful foliage, picturesque dwellings, the brilliant flora, and myriads of gorgeously plumed birds present an ever-changing panorama of loveliness. Soon the diet of *tortillas, frijoles,* and rice, and steady grind of the saddle, and the stings of numberless insects by day and by night, spoil the effect of the landscape, and before the end of the second day the screams of the vari-colored macaws flying in pairs across the sky, the chatter of monkeys in the trees, the bright plumage of the big-billed toucan, and the golden-tailed *Oro pendulum,* singing in melodious con-

TRAIL THROUGH LOWLANDS. TREES COVERED WITH ORCHIDS AND VINES.

RAILWAY AT CHOLOMA WITH U. S. SOLDIERS GUARDING AGAINST INTERRUPTION OF TRAFFIC.

ULUA RIVER AND POTRERILLOS CAMP OF GENERAL CARIAS.

CEIBA, HONDURAS. BATTLE WAS FOUGHT AROUND TRENCHES IN WOODS AT THE LEFT.

English officials had taken charge of that port and had shipped the Honduran army out of Cortez and San Pedro and dumped it off at the end of the railroad. When we reached that point a most interesting sight met our eyes. On the opposite bank of the river was the camp of the Government forces, with a line of entrenchments stretching along the bank for a half mile. All the boats were moored on the farther side of the river; more than a thousand riflemen were in their pits and trenches, ready for battle; nine machine-guns and two 2-lb. cannon were loaded and trained

tralto from above its wonderful swinging nest at the end of the highest branches, have become commonplace.

By the end of the second day the traveler finds his chief interest in the application of witch-hazel to his sore muscles and iodine to his insect-bites, for the bane of existence in Honduras is the ravenous nature and overwhelming numbers of the insects. The timber-tick is always present in full force, the nimble flea fills every habitation; and along the coast the mosquito and the tiny sand-fly add their due portion to the sum total of human misery. But for objection-

ableness no other insect can compare with the *garrapata,* minute representatives of the tick family, which wait in hordes at the end of every branch along the trail to drop upon the passer-by, scatter over his person, and bury their screw-like heads in the flesh. Against them man has no protection but tobacco-juice, though by keeping one's clothing saturated with this drug one may pass through the interior with a small degree of freedom from these pests. Another very interesting insect is the *nigua,* which is almost microscopic and hence difficult to detect. Its principal business is to bore into the flesh at the side of the nail, usually on the toes, and deposit its eggs, which hatch there and produce sores similar to boils; the only remedy is to cut out the larvae, often a quite painful operation.

Outfit and Medicines

For the benefit of those contemplating a trip into the interior it may be well to state that the outfit for the journey is best obtained at San Pedro—mules, *mozos,* and all. With proper credentials it is often possible to rent animals at about one peso per day. *Mozos,* or native attendants, may be engaged at the same rate. Often, however, one must purchase animals, and a good mule costs about ₱200; horses, ₱25 to ₱100. A saddle-animal, a pack-animal, and a *mozo* are required for each person, unless the party consists of more than three, in which case the proportion of pack-animals and *mozos* may be decreased.

The essential articles of clothing are: light underwear, khaki suit, good waterproof hat with broad brim, high boots; and a good raincoat kept strapped to the saddle—preferably a black rubber coat, as 'oil-skins' and cravenettes are but slight protection against a prolonged tropical down-pour. It is not advisable to carry any luggage which can be damaged by rubbing on the outlandish native pack-saddles or crushed by tight binding-ropes. Use heavy canvas bags or wrap in a bundle and cover with oil-cloth. It is well to lay in a small supply of canned goods and bread; for, though there are places along the trail where travelers regularly spend the night, noonday finds one far from habitations and the fare at the lodging-places is not sumptuous.

Do not forget a small assortment of bandages, cotton, court-plaster, surgeon's plaster, vaseline, carbolic acid, and witch-hazel; quinine, to allay fever; iodine, potassium permanganate, and potassium bisulphate for stings and bites of insects or reptiles. I always carry an ounce or two of aconite to ward off colds. Five or six drops of this every couple of hours when one feels a cold coming on will do no injury and is a sure preventive. For sleeping purposes a pair of heavy blankets and a hammock or folding cot make up the equipment. It is not a bad idea to carry a 0.38-calibre revolver for protection against unkindly disposed natives, and as a means of killing game. Deer are plentiful through the country; peccaries, tapirs, coyotes, jaguars, and other animals are found in some parts of the interior; the iguana, a species of lizard which attains a length of three to four feet, is quite common, and the natives esteem its flesh a delicacy; squirrels abound through the forests; and there are ducks, geese, and numerous game-birds, of which one of the most common is the *chachalaka,* which resembles the wild turkey.

The Honduran native is not so good a prospector as the natives in many parts of Mexico. He does not use his eyes and head to so much advantage in his work as the average Mexican, and does not recognize the different formations so readily; hence the country has not been nearly so well prospected as Mexico, and there is probably more chance of reward for intelligent prospecting.

A cement for making tight joints in pumps, pipes, etc., is made of a mixture of 15 parts slaked lime, 20 parts graphite, and 30 parts barium sulphate. The ingredients are powdered, well mixed together, and stirred up with 15 parts of boiled oil. A stiffer preparation can be made by increasing the proportions of graphite and barium sulphate to 30 and 40 parts respectively, and omitting the lime.

Oilfields South of Coalinga

By Wm. Forstner

In the middle of October 1910, the drill at the well of the Coalinga Oil Co., in the N.E. ¼ of section 22, T. 21 S., R. 15 E., cut through a peculiar black greasy material at a depth of 3750 ft., 2850 ft. below sea-level. This material came up, some on the bit, but mostly on the line, while drilling at 3750 to 3790 ft. During the latter part of the drilling it was nearly exclusively on the line, about 20 ft. above the tool, at a point where the swaying of the line was liable to throw it against the walls of the bore-hole. Past the depth of 3790 ft. no further black sticky material was brought up in drilling. From 3720 to 4154 ft. the well went through shale, with only one stringer of sand 2 ft. thick at 4002 to 4004 ft. It is probable that the black greasy material came from a bed at or near 3750 ft. depth. The thickness of the bed can not be estimated from the data at hand, but it is probably not over 20 ft. Some of this material was forwarded to me for investigation. It has been so thoroughly mashed that there is no possibility of judging of its structure, and resembles axle grease removed from an axle; its color is black, it has no smell, and it is greasy to the touch, staining the fingers black. Adding chloroform to it in the test tube, the color of the solution is black instead of brown, as is the case with oil. No grease appears on shaking in the upper part of the tube, but a dark-brown film, insoluble in chloroform is leached out of the mass by the chloroform and is deposited on the tube. I took the sample to Abbot A. Hanks, in whose laboratory the further investigation was made. Of the entire mass 70% was found to be of inorganic origin, crushed shale and considerable iron. With a strong glass a number of particles of steel from the bit could be distinguished. Dissolving the organic matter and evaporating the solvent, it was found that 24% was a light yellow, viscous, unctuous material, with a taste resembling vaseline, soluble in CS_2, in boiling ether, but insoluble in cold alcohol; and 3% a darker material, soluble in CS_2, in chloroform, ether, and boiling alcohol, but insoluble in cold alcohol. All the native bitumens are soluble or practically so in CS_2, except the 'pyro-bitumen albertite,' but differ in their behavior toward other reagents. Paraffine and ozokerite, its solid native hydrocarbon, are soluble in ether, but only sparingly in boiling alcohol, not over 3%, and insoluble in cold alcohol.[2] Petrolene, the liquid part of the asphaltic solid hydrocarbons, is soluble in ether and chloroform, and dissolves in strong alcohol. It stains paper like oils, and burns with a strong smoke.[3] Both these latter characteristics were absent in the material tested. Asphaltene, the solid part of the asphaltic hydrocarbons, is soluble in chloroform and insoluble in strong alcohol. The results of these tests appear to me to justify the suggestion that the greatest portion of this material has a paraffine base, and that the 3% of darker material represents the portion with an asphaltic base.

On November 20, 1910, the well of the Bohemian Oil Co., in the S.E. ¼ of the same section, reached the oil sand at a depth of 3700 ft., 2900 ft. below sea-level. It showed 35 ft. of oil sand. The oil is of very high grade, between 35 and 36°B. A sample of this oil was submitted by me for a test to Abbot A. Hanks, in order to determine its character, and he reports that this oil is of an asphaltic base. Judging from the topographic map issued by the U. S. Geological Survey, the collar of this well cannot be over 100 ft. below that of the Hub well. The Bohemian lies on the eastern flank close to the axis of the Jacalitos anticline, as outlined on the map of the U. S. Geological Survey Bulletin No. 396, while the Hub well lies one-half mile northeast of that axis. It must be further noted that the latter well lies close to and north of an east and west

line of disturbance in the formation, which has a steep dip to the north. This disturbance may account for the occurrence of the bed of solid hydrocarbons in that well.

All native bitumens originate in petroleum, and are products of its metamorphosis, depending for their character on that of the petroleum from which they are derived, and the environment to which it was exposed during the last periods of the time when the changes were going on. Solid bitumens are, apparently, formed from all types of petroleum. Ozokerite consists of solid paraffine, and is plainly derived from paraffine petroleum. From the non-paraffine oils are formed the asphalts of various names and characteristics.[4] All are formed by oxidation and evaporation of liquid petroleum which continually oozes from deeply seated or better covered deposits into other strata or into fissures where atmospheric influence or evaporation are free to act. When evaporation alone takes place, the solid constituents are merely concentrated with the production of the solid hydrocarbons, ozokerite, gilsonite, grahamite, albertite, and similar compounds.[5] It must be further noted that the solid hydrocarbons obtained as residue in the distillation of crude oils are actually contained in the petroleum, and are not the product of decomposition during distillation. They have actually been separated without distillation.[6] The nature of the crude petroleum can be changed by its diffusion through media sufficiently fine-grained and porous to afford capillary spaces, which can cause a separation of the constituents of any mixture, provided these possess different surface tensions. The members composing the natural oil may be grouped as paraffine or saturated hydrocarbons, unsaturated hydrocarbons, sulphur, nitrogen, and oxygen hydrocarbon compounds. D. T. Day early observed that the unsaturated hydrocarbons are less diffusible than the paraffine hydrocarbons.[7] In the Hub well the bed of solid hydrocarbons was found, as above stated, near the top of a thick belt of shale, which would afford the conditions required for the accumulation of the paraffine hydrocarbons in the oils, provided such were present in the oil. In this respect it must be noted that the examination of the California oils, in general, does not show the presence of hydrocarbons of the paraffine series, and if any are present they are contained in the lighter gasolines from this petroleum.[8] Therefore the only explanation available is, that during the diffusion through the shale underlying the bed of solid hydrocarbons of the lighter constituents of the petroleum, the saturated hydrocarbons (paraffines), diffusing more readily than the unsaturated hydrocarbons, accumulated in the overlying sand; and that this diffusion occurred here locally, because, for some reason or other, the shales were dry, and therefore allowed the diffusion.

The oils containing hydrocarbons of the paraffine series as yet found in the Coalinga field, come from the lowest Eocene or upper Cretaceous. The oil at Oil City, in section 20, T. 19, R. 15, north of Coalinga, which contains such hydrocarbons, is derived from the upper Cretaceous.[9] That of the upper Kreyenhagen wells in Canoas canyon, section 33, T. 22, R. 16, which is of a paraffine base, is in wells that start in the lower Eocene shales and therefore derive their oil from the lowest Eocene or upper Cretaceous. As the Hub found the oil sand of the Bohemian over 600 ft. below the bed of paraffine bitumen, it is hardly conceivable that these bitumens are derived from lowest Eocene or upper Cretaceous oils. Besides, the surface indications tend to the suggestion that these formations have been eroded or are absent in this territory.

The determination of the geological conditions governing the oil occurrence in this vicinity is rather difficult. Most probably the Waltham and Jacalitos creeks are the eastern parts of one of the depressions in the Mount Diablo range through which the sea in former geological periods had access to the Great Valley of California, and it appears to me most probable that at one time the main depression was to the south of Currie mountain along the present line of Carey and Salt Lake creeks, tributaries of the Jacalitos creek, and that subsequently Waltham creek, the outlet of Waltham valley, cut its way through the northern portion of Currie mountain. At Devils gorge (Jasper gorge on the map in U. S. Bulletin No. 396) the Vaqueros lies directly over a narrow exposure of the Knoxville (lower Cretaceous) dipping very steeply northeast, which is in turn underlain by the Franciscan which forms the east slope of the main range. Between the Devils gorge and Castro creek, in the southwest corner of section 3, T. 22, R. 15, the Franciscan is overlain by alternating beds of clay shale and sandstone, probably belonging to the Jacalitos formation, and the latter either overlaps the intervening Mesozoic Eocene, and lower and middle Miocene formations, or these were eroded. West of Castro creek, heavy beds of shale overlie the Franciscan. They are found on both sides of Carey creek and the overlying sand gives a strong reaction for bitumen. This shale belongs apparently to the same formation that covers the top of the range, and is found on the west slope overlying the Vaqueros near the Stone Canyon coal mine, which would place the age as Miocene. It is reasonable to suggest that in lower and middle Miocene times the entire range was under the sea, and that subsequent to the middle Miocene uplift all the younger formations were eroded from the east flank of the Mount Diablo range.

A summary of the diastrophic movements in this region may help to a better understanding of the conditions. From the distribution of the Cretaceous in the Coast ranges it is evident that a part of that range did not subside below sea-level during that period, especially in the southern portion, the lower Miocene in many places being found resting on the Franciscan. During the Eocene the Great Valley formed an arm of the ocean, with an outlet to the south. The relation of the Miocene and Eocene suggests that, although no profound disturbances occurred at or near the close of the Eocene, differential oscillations and intervening periods of quiescence occurred. Since in many places the Eocene was greatly eroded before the deposition of the Miocene, subsequent to the middle Miocene, an uplift must have taken place, raising all of western California above the deep-sea, and partly above sea-level into the zone of erosion. Later subsidence never brought the east flank of the San Joaquin valley down to deep-sea level, the upper Miocene and later formations being characteristic littoral deposits. Then followed the post-Miocene uplift of the Coast range, and the post-Miocene interval of high altitudes and erosion. This period of erosion must have lasted a long time, for in places the upper and middle Miocene was entirely removed. After the post-Miocene interval of high altitude, the Pliocene period of depression occurred. Most probably an orogenic movement took place at the close of this Pliocene period of sedimentation, along a large part of the West Coast, which caused the upthrust of the Mount Diablo range. These mountain-making movements were, however, not adequate to efface the peneplain formed in the post-Miocene period of erosion, and it was extended between the bolder masses of the disturbed districts. At the close of the Pliocene the topography was that of an approximate peneplain with numerous peaks and ridges above the general level, while the coast had the aspect of an archipelago.[10] During the long period from the end of the Eocene to the present time, this region then has been submitted to a series of elevations and subsidences. During the former a greater or less part of the older formations was eroded, while all these movements of the earth crust were accompanied by folding, and in many cases faulting, of the strata.

When discussing the conditions of oil occurrence, especially in a new field, it must be remembered that the underground conditions are far from regular, and this the more so where, as in this case, all indications point to local disturbances. The developments in the well of the Pulvadore Oil Co., in section 2, T. 21, R. 16, indicate that possibly here the oil measures lie nearer the surface than to the north or south. This well lies about three-fourths of a mile east of the axis of the Coalinga anticline, and in it at a depth of less than 1500 ft. oil measures were found. To the north the Mohawk No. 1, in section 12, T. 20, R. 15, one-quarter mile east of same axis, showed the first oil sand at 3700 ft., and was finished at 3955 ft. The Southeastern No. 1, in section 18, T. 20, R. 16, about the same distance east of the axis, reached the first oil sand at 3600 ft., and was cemented off at 4272 ft. To the south well No. 1 of the Coalinga Kettleman Hills, in section 2, T. 22, R. 17, about one-half mile east of same axis was at 2965 ft. deep in blue shale, with gas but no oil. To the north the axis of the Coalinga anticline is dipping southward, to the south it is dipping northward, and the surface indications therefore suggested that in the vicinity of the location of the Pulvadore well the oil measures would lie deeper below the surface.

There are many unexplained occurrences in this field, and the data at hand are not sufficient to attempt an explanation. The oil operators are unwilling to give access to their logs, notwithstanding repeated requests, and friendly intervention. I have been only able to obtain the log of one well, and one log is entirely insufficient to draw any conclusions from on this subject.

The Hercules Mill

By W. A. Scott

The new mill of the Hercules Mining Co. was built last winter, and began operation in April. The plant is on a steep hillside at Wallace, Idaho. The mine is in the vicinity of Burke, and the ore is taken out through No. 4 adit-level. At the portal of this level is a sorting plant, where the waste is taken out, and the high-grade ore and mill stuff are separated. The mill ore is passed through a crusher and reduced to 2½-in. size. In this form it is transported to the shipping bins at Burke over a 3500-ft. aerial tramway. It is hauled in bottom-dump railroad cars from Burke to the ore-bins at the head of the mill. These bins have a capacity of 1500 tons of ore. The mill is built in two sections, each being housed in a separate structure, the two being 80 ft. apart. The section immediately below and connected with the ore-bins contains the crusher, rolls, trommels, jigs, classifying screens, and Huntington mills; the second section is designated as the slime-plant, and contains settlers and classifiers, traveling screens, tables, and vanners. The ore is discharged from the bins through plunger-feeders upon a 70-ft. belt-conveyor that extends lengthwise of the bins; this conveyor discharges upon another conveyor that travels at right angles to the first, and delivers the ore to a 4-section system of trommels—two 12-mm., one 20-mm., and one 36-mm. The oversize from these goes to a fine crusher; the undersize from the 20 and 36-mm. trommels goes to the jigs, while that of the 12-mm. passes to three Franz traveling screens of 4, 8, and 20 mesh, respectively. The oversize from the Franz screen goes to the jigs, while the undersize is conveyed in launders to the slime-plant. The tailing from the coarse jigs is returned to middling trommels; the jig middling is dewatered by a shaking-screen, and goes thence to a set of rolls, following which it is passed over traveling screens, the oversize from which is reground in Huntington mills; the undersize, together with the 20-mesh Huntington product, passes to the slime-house. The most important product of the mill is made in the 16 two-compartment jigs, and consists of the oversizes of 4, 8, and 20-mesh screens. The ore constituents comprise lead, silver, iron, and a small percentage of zinc, in a silicious gangue.

The slime-house material, consisting of the undersize from all 20-mesh screens, and the 20-mesh product of the three 6-ft. Huntington mills, is classified by traveling-screens, 4-spigot settlers, and Callow tanks, the different classes thus obtained being concentrated on tables and vanners. For this work there are 8 Wilfleys, 8 Franz tables, and 6 vanners. A novel feature of this part of the mill is the work of the Franz tables, designed by Frank Franz, superintendent of the plant. This table has on its deck a system of parallel riffles, or grooves, directed toward outlet slots through which the coarser product is discharged; also a pair of pans, and deflector ribs for directing the stream of finer mineral to the pans where the finer concentrate and gangue are separated. The tail-end of the deck may be adjusted with respect to the other part of the deck, to regulate the speed of concentration of the material. These tables appeared to be effecting a clean separation, and were operating on the second, third, and fourth-spigot product from the settling tank. The other tables and vanners were performing in the usually effective manner.

HERCULES MILL AND SLIME-PLANT, WALLACE, IDAHO.

The mill machinery is operated by electric motors, distributed advantageously throughout both sections. The present capacity of the plant is 400 tons per day, though this is soon to be increased to 600 tons. The mill-work effects a concentration of 8 tons into 1 ton. In the accompanying illustration may be seen the shipping-bin with two lines of conveyors extending at an incline from the ground to the top of the building. This structure is 20 by 40 ft., and 40 ft. high, divided into three compartments—one each for jig concentrate, slime product, and tailing. Each conveyor has a length of 110 ft., one carrying the two classes of concentrate to the bin, and the other the mill tailing, the latter to be hauled or laundered away, and not deposited in the stream. A 60-hp. steam-boiler is in position in a room for that purpose, to serve in heating the building during the cold weather.

Vertical shafts frequently must connect with inclines after the vein has been reached. In many mines an underground hoist and loading pockets are used and the ore is transferred from one skip through pockets to another. At the Harvard mine in Tuolumne county, California, the skip makes a continuous journey from the bottom of the incline up the vertical shaft to the surface. This is made possible by continuing the guides of the vertical shaft down the incline and using no track in the latter. Instead of shoes, wheels are placed on the side of the skip and in the incline the rails, forming the continuation of the guides, are hung on posts rather than set on ties. The whole arrangement works out simply and is an effective means of meeting a common problem.

Concrete in Mining

By George S. Rice

*Concrete is not unknown to miners; apart from its uses in foundations for machinery, it has been employed for many years to plaster mine stoppings and dams built of brick or stone, to render them comparatively water or gas-tight. Within the last few years, contemporaneously with the advance of the science of reinforcing concrete, the general use of concrete in mining operations has been enormously extended. Today practically all foundations for mine buildings and machinery are built of concrete, and many buildings, coal-bins, lofty chimneys, and even a large anthracite breaker have been built of reinforced concrete. In many of the large new mining plants, concrete has entered extensively into construction underground, replacing wood, iron, brick, and stone. Its use for various purposes in and about the mines is rapidly extending, as its merits are better understood. The possibilities of underground application appear to widen constantly, suggesting more than mere economies and even affecting fundamentals of mining.

In the short compass of this paper, the present numerous applications and future probabilities of mine uses can only be enumerated and briefly touched upon in a suggestive way.

Shaft-Sinking

In Europe, mining operations have been regarded as of more or less permanent character, particularly in coal mining, owing to the great number of seams in the coal measures. Hence for many years shafts have been sunk using brick or stone for lining, such shafts being circular or elliptical in cross-section. Where it has been necessary to employ iron or steel casings to pass through water-bearing strata, permanent inner linings of stone or brick have been used. In some recent shafts concrete has been substituted.

In this country, until the past few years, it has been, without exception, the practice to employ wood linings, the shafts being rectangular in cross-section. Water-bearing silt or quicksand were generally avoided, if possible, and where water was met in shaft-sinking, no attempt was made to keep it out, as in the European shafts.

In some instances where the surface quicksand proved shallow, concrete dams were constructed inside of timber lining or coffer-dams. Generally these inner linings or dams were circular or elliptical in section and massive, so that reinforcement was incidental.

Example of a Reinforced-Concrete Lining.—In sinking the air-shaft of a coal mine in Illinois, in 1906, through the surface silt, I used a reinforced-concrete lining, Fig. 1, of rectangular section and sufficient strength to resist the water-pressure, so as to keep the air-shaft dry. This is an important matter if the shaft is to be used for 'intaking' air, since in a wet shaft, masses of ice accumulate in cold weather, thus restricting the ventilating current or stopping it, with serious results. The inner lining was put in after the shaft had been forced through the soft silt, and the outer wood curbing rested on the rock. The latter was a fissured limestone, so the shaft was sunk about 8 ft. farther into the shales below, where a good foundation was prepared for the concrete lining.

As the water rained down the shaft in streams, while putting in the massive concrete foundation, the sinking pump was temporarily checked in laying the successive courses, and the water allowed to rise above the level of the course to be laid, so that the concreting materials could be placed behind the form in water without currents. The concrete was then carefully rammed against the shale and rock to make tight joints.

When this foundation had been brought up to the level of the wood curbing, preparations were made for building up the thinner reinforced-concrete walls, which were but 15 in. thick at the bottom, and 9 in. thick at the top, 40 ft. above. Diagonal wood strips were nailed on the inner face of the wood curbing and to these a tight lining of tongued and grooved flooring was nailed. This deflected the water-streams to the bottom of the lining, and short pipes were placed through the concrete forms at a number of points around the shaft, so as to discharge the water from behind the wood lining into the open shaft. By this method the reinforced walls were erected with freedom from running water.

The reinforcement consisted of deformed bars placed horizontally and vertically near the inner face (that is, toward the centre of shaft). The vertical bars (½ in. square) served only to bond the courses; the horizontal bars (⅞ in. square) were spaced close together at the bottom, and farther apart at the top, according to calculated water and earth pressure, assuming no help from the outer wood curbing. The horizontal reinforcement bars were bent around

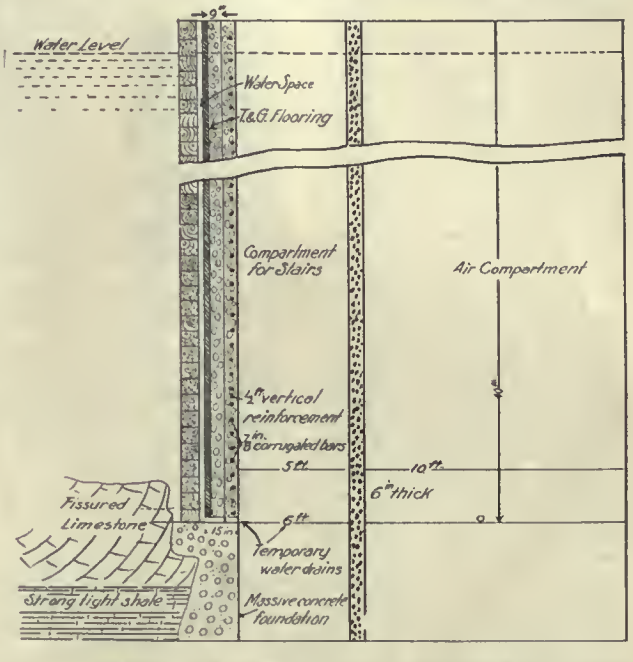

FIG. 1.—SKETCH OF RECTANGULAR REINFORCED-CONCRETE SHAFT-DAM TO WITHSTAND WATER AND GROUND-PRESSURE.

at the corners of the shaft, which were beveled. The shaft had two compartments about 9 by 10 ft., and 9 by 5 ft. in the clear, with a 6-in. concrete partition between.

When the concrete had sufficiently hardened, the drainage pipes were plugged, and the walls then served their purpose as a dam. There was a slight seepage at several points, but this gradually stopped.

Drop-Shaft Sinking

Where the glacial drift or water-bearing silt is very deep, special methods of shaft-sinking have to be employed. The freezing system and the drop-shaft system have been highly developed in Germany and France, and to a point where both are very successful. Reinforced concrete is adaptable for linings in connection with either system, but it has not as yet been employed to any considerable extent.

In this country, little has been done with either of these systems, chiefly because there has been no general need, as shaft-sinking conditions are ordinarily easy. More recently there has been occasion for penetration of water-bearing silts in the Lake Superior iron mines, and one reinforced-concrete casing has been successfully sunk. The plan of the casing was similar to the ordinary drop-shaft casing of brick so extensively employed in England, namely, to build on top of a steel shoe which drops as the excavation proceeds. Skin resistance to descent of the 'drop-shaft' is the chief obstacle usually encountered so far as the casing is concerned, and this has to be overcome by weighting.

The concrete bridge pier caissons sunk in Western river silts, and the caissons used in the vicinity of New York

*Address delivered by permission of the Director, U. S. Bureau of Mines, before the National Association of Cement Users.

for shafts preliminary to tunneling, are of the same nature as drop-shaft casings, except that their greater size and weight, relative to depth, makes the problem of sinking them simpler. The small caissons sunk for foundations of high buildings are more akin to mine shaft-sinking, except the depth is usually less, so air-pressure can be used to hold back the water.

Drop-shaft casings can be sunk by dredging with clam-shell or orange-peel buckets under water when the material is silty or sandy. If complicated by glacial boulders bedded in hard clay or natural cemented material, it is necessary, when the work is too deep for air-pressure, to pump out the water and excavate by hand with the assistance of explosives.

The method of using reinforced-concrete casings seems applicable to many situations where it is necessary to sink through bad ground, modifications being made to suit the condition of the sand or glacial drift that may be encountered.

Cementation of Wet Ground

A most interesting method used in connection with shaft-sinking or tunneling through water-bearing ground has been developed in the Pas-de-Calais coal district of France, which is termed 'cementation.' The coal measures of the district are overlain with bedded marls and chalks, more or less fissured, and the fissures in some places are so filled with water that ordinary methods of shaft-sinking would fail. Heretofore, the freezing system has been successfully used, but the new cementation method, I have been informed by French officials who had used both methods, could be employed at less cost.

In one instance, the cost of cementation through 343 ft. of water-bearing ground was $13,200. Interesting particulars of this work are given in a paper† by J. Lombois, principal engineer of the Mines de Bethune.

Briefly, the process used by this company is to drill a set of holes, six in number, in the water-bearing ground, arranged in a circle, surrounding the site of the proposed shaft, and then to pump a cement grouting through the holes until the fissures and interstices are filled. Shaft-sinking is then carried on as it would be through ordinary rock strata. The system seems applicable to many situations where water is encountered in either shaft-sinking or tunnel-driving in broken rock.

Overcasts, Stoppings, and Dams

Concrete has already been adopted by many mine operators in the building of overcasts (air-current crossings). These have usually been of massive construction. If reinforcements were employed, the cost of overcasts, also of stoppings and dams, might be considerably reduced. Some operators use small coal for stoppings in place of crushed stone. If the coal is sufficiently tough and properly screened, in massive stoppings this is economical, but often too much coal-dust is used, so that an excess of cement is required and the concrete is very weak. Such concrete is not suited for stoping or water dams where there is likely to be much pressure thrown upon them.

Concrete Timber-Sets

There appears to be an even better opportunity for the development of a system of outside-constructed reinforced timbers for passageways than there is for room-props, since timber-sets are intended for permanent use and greater strength is required. In collieries, each timber-set consists of a collar and two posts or legs. The collar is perfectly square in cross-section; the legs may be either round or square. It would be necessary to have legs of different lengths, but this entails no particular difficulty; small differences are easily taken care of by picking the footing deeper, or wedging over the top of the collar. That there is a field for the use of concrete timbers is shown by the increasing use of I-beams for collars, and for legs. Concrete timbers for equal strength would be more durable and should be cheaper.

The opportunity for use of concrete posts and timber-sets in certain kinds of metalliferous mining appears to be as great as in collieries. Often great strength is needed, and in some parts of the country, as in the Southwest mining districts, big timbers are difficult to obtain and very expensive. Crushed rock for concrete is nearly always at hand in metal-mining operations, and portland cement can now be obtained at moderate price in any part of the United States. Reinforcing material is often found in the scrap-iron pile. In some cases, large concrete timbers could be built in place, but in many instances, owing to the condition of the roof, it would be necessary to have the full strength of a concrete timber or beam at the time of erection; hence the necessity of having concrete timbers constructed and seasoned in advance of setting.

Concrete Ties

Among other mine supplies subject to rapid deterioration, there is the considerable item of track ties. Frequently there are miles of track in a mine, especially in a large colliery, for which an immense number of ties is required, running into the tens of thousands in a single mine.

Ties have a shorter life than props or timbers, as they are subject to both wear and rot. In most mines the floor of the roadway is generally damp, and in the case of bituminous mines it is purposely wetted in order to lay the dust. This damp condition favors the rotting of ties. Ties, as a rule, are made of oak, preferably white oak, and are either split or hewn like railway ties. They have to be renewed at intervals of 2 to 4 years. Here then is an opportunity for concrete ties if they can be adapted to the conditions. Possibly, if made light and durable enough, they could be used for temporary ties and be taken up and relaid like the rails in other parts of the mine when the room was finished.

In the development and testing of concrete props, ties, timbers, as well as the concrete linings previously mentioned, there would appear to be need of work on the part of the United States Bureau of Mines to undertake tests under practical conditions in order to benefit the mining industry.

The aggregate of new construction for mining plants annually reaches large sums. In the case of large modern collieries, a single plant may involve, exclusive of machinery, for outside buildings and miners' houses, from $100,000 to $200,000. Generally the construction of the mining plant is under the direction of a mining man, and the buildings are treated as incidental to the machinery and mine development. Under such circumstances, the construction of the general buildings is not given the thought and attention that they warrant, and buildings are often makeshifts. If concrete builders would give the subject the same study that they give to bridges and buildings for manufacturing, and be prepared to take up the construction of mine buildings of various kinds with promptness, there appears to be a large field of usefulness, productive of improved construction and adequate fire protection.

The use of lignite in gas-producers, with subsequent employment of the gas in gas-engines, continues. Satisfactory progress in this direction has been made at several large establishments. It is likely that the use of a tar-less gas-producer, such as has been in successful operation on Colorado lignite, would be advantageous in Texas. It is also suggested that an effort be made to save the ammoniacal liquor from the gas-producers and use it in the manufacture of ammonia compounds, such as anhydrous ammonia, sulphate of ammonia, etc. The briquetting of lignite does not seem to appeal to the trade, and there is no plant in operation in the State.

Accidents in mines are more common on night than day shifts, and at one large mine where careful records have been kept, 60% of the accidents have happened in the first few days following a change of shift. It takes a short time for the men to accustom themselves to sleeping by day, and there are always some who work 'long shift' following change-day.

†*Bulletin de la Societe de L'Industrie Minerale*, Vol. IX, 1908.

The Copper Situation

The drastic measures employed last month to bring consumers into the copper market, the price being broken to less than 12c., evidently failed to even temporarily bolster the situation. Copper is working to another crisis, to the point where a group of high cost producers must suspend operations for the time being. During 1910, the accumulated visible supply reached a high figure in July of 170,640,678 lb. It was during the latter part of 1910 that the co-called curtailment policy was inaugurated and the hope generally expressed that the output would be regulated and the metal market materially strengthened.

Now the copper surplus is again reaching a danger point. Instead of the hoped-for decrease, the Producers' Association figures for March showed an increase of 3,547,974 lb., making accumulated stocks total 165,555,908 lb. The surplus abroad as of the same date is 173,687,360 lb., making a world surplus of 339,243,268 lb. While the dead weight of the accumulated copper is a burden, it is the continued high-pressure production that renders the situation acute. At most, accumulated copper means a world's supply for not more than sixty or ninety days, but it seems now to be impossible to regulate production, especially so long as the porphyry properties dominate the market. These mines can show profits only when operated on a gigantic scale, and the loss entailed by partial or complete shut-down must be estimated in proportion. The Nevada Consolidated's quarterly report, just issued, shows a production for the first quarter of 1910 of 15,893,743 lb., produced from ore averaging 1.84% at a cost of 6.99c. per pound. It is evident from the company's statement that the property is capable of still greater things. On the Liberty Pit 8½ acres has been stripped of overburden, and this part of the ground is expected to furnish 2000 tons of ore per day when called upon. The entire plant will be using fuel oil instead of coke by July. Utah Copper shows a production during the same period of 21,296,709 lb., costs being 8.434c. per pound.

The figures are not particularly important for comparison and analysis, save to officials and stockholders. The general public and the holders of shares in other concerns need study results only to estimate the possibility, or rather the impossibility, of regulating output. It is so patent that mines and plants, such as the two leading Guggenheim properties mentioned and others now in the making, and upon which millions of money have been expended, must operate at a profit, if possible, at some loss if absolutely necessary, but in any event, must keep going to avoid the terrific loss entailed by anything approaching a shut-down. Copper metal and copper shares can improve and advance from the present position only by a working out of the law of the survival of the fittest. The high-cost producers will have to do all of the curtailing.

Gold Mining in Korea

The most important gold mines in Korea are operated by American companies. The important Oriental Con. mines at Taracol and Tabowie have often been described and the Chicksan mines south of Seoul were described in the *Mining and Scientific Press* of April 1. Another important mine is the Suan copper and gold mine. This was formerly operated by the Korea Syndicate, an English company which did not meet with the expected success, and in 1908 sold the concession to Collbran & Bostwick, a well known American firm which has done extensive engineering work in Korea, who in 1909 erected a 20-stamp mill on the property and in 1910 added 20 more stamps. The ore offers a good deal of trouble in milling, as it is difficult to save the copper, and bismuth, present in the ore, interferes with the catching of the gold. The mill treated 32,793 tons of ore during 1910, 389 tons of concentrate was shipped to Tacoma, together with 707 tons of high-grade ore. The bullion produced in the mill was worth $263,482, or $8.03 per ton, and the ore and concentrate realized $104,468. The profit was $215,151, out of which $64,597 was used for capital expenditure, chiefly for the purchase of the additional plant, and $100,000 has been distributed as dividend. As regards the extraction, 67% of the gold content is recovered on the plates, and 11% in the concentrate, making a total of 78%. The recovery of copper is only 18%, which shows that the concentration plant is unsuited to its work, losing not only copper, but also gold. The ore reserve on December 31 was 190,000 tons assaying $13.42 gold and 1.76% copper. Since then rich ore has been found on the 400-ft. level.

Manufacture of Coalite a Failure

About two years ago information was published about 'Coalite', a patent fuel, that was being boomed by company promoters in London. It now develops that, so far, it has been a ghastly failure. The promoters started with too much mystery and with too many claims. As was previously mentioned, coalite is a semi-coked bituminous coal, the coking process being conducted at a lower temperature than when gas coke or metallurgical coke is to be produced. Only one-half of the volatile matter is expelled, so that the product gives a cheerful flame in the open grate; while the coal is made sufficiently porous to allow the requisite amount of air to come in contact with it, in order to prevent the formation of smoke and soot. Theoretically it was an ideal fuel for the Englishman, who loves an open fire, and who hates closed stoves, hot air, and steam-heat. Enormous amounts of capital were raised and spent on plants in various parts of the country, and quite a number of eminent scientists and manufacturing engineers lent their names to the scheme. The true facts have now come out, and Herman Clarke, who was recently appointed manager, has given a plain, unvarnished tale to the unfortunate shareholders. He reports that 100 tons of bituminous coal will give 72 tons of coalite, 65 tons of gas coke, and 70 tons of metallurgical coke, according to the method of treatment. The corresponding amounts of by-products are 5000, 11,500, and 10,500 cu. ft. of gas; 22, 9, and 8 gal. of liquid hydrocarbons, and 16, 26, and 27 lb. of sulphate of ammonia. The candle-power and thermal efficiency of the coalite gas is higher by 30% than that of the other gases. It has been found that coalite is of no commercial value as an adjunct of gas manufacture, and all of the plants erected at gas works have been making a dead loss. As far as the coalite itself is concerned, it is found, under present methods, to be much too brittle, and quite one-half is lost as dust, fine, or slack, that brings no price in the market. Mr. Clarke is of opinion that the only hope is to centre operations on the improvement of mechanical handling, in order to produce a strong enough material, for, as a household fuel, coalite certainly has a promise. Two years ago there was a controversy as regards the value of the patents, and it was generally argued that they were not valid, for the process is simply a reversion to the old methods involved in gas manufacture and in the production of metallurgical coke. Modern methods adopted in these two industries naturally aim at a hard coke produced at a high temperature, and they have been successors to the older and less complete reactions, now represented by coalite. No lawsuit was ever started with regard to the validity of these patents, because it was to nobody's interest to do so. Therefore, the question of the validity never came before the courts.

Transvaal Gold Production

The Transvaal gold production for the month of March is given as 676,065 oz. of fine gold, valued at £2,871,740, being £277,106 more than the output for February. This output constitutes a record, being £65,505 more than for December 1908. Negotiations are in progress between the Union Government and the Government of German Southwest Africa on the subject of the recruitment of natives. The Transvaal Chamber of Mines has requested that the

question of reciprocity also be discussed. The new post-office bill provides that the Governor general may make regulations providing that gold and diamonds shall be carried exclusively through the medium of the post-office.

The Motter Method

By Paul W. Gaebelein

A lot of 2000 lb. of ore from the Gubucia mine, at Ocotlan, Oaxaca, Mexico, was recently treated by the Colorado Metals Extraction Co. of Denver, at its 20-ton plant, in which the Motter process is used. The ore was a complex sulphide, an assay of which showed the following: Gold, 0.11 oz.; silver, 5.4 oz.; lead, 3%; copper, 5.9%; zinc, 10.5%; iron, 13.2%; sulphur, 14%; silica, 52%. The treatment consisted of dry-crushing to 20 mesh, roasting in the Motter furnace, forming sulphates of copper and iron; leaching to recover copper, and concentration to separate lead and zinc, as these were the metals which had proved difficult to recover. After concentration, the following results were obtained: Lead concentrate: silver, 36.3 oz.; gold, 1 oz.; lead, 76%. Zinc concentrate: silver, 7.4 oz.; zinc, 46.6%; iron, 2.9%; silica, 14 per cent.

No attempt was made to recover gold by amalgamation, as practically all the gold and silver went into the lead concentrate. The copper, of which 95% was recovered, was obtained as high-grade cement copper. The zinc concentrate was cleaned of magnetic iron by magnetic separation, and the product, 46.60% zinc, is a high-grade product. By a more careful concentration, this percentage could undoubtedly be raised to 53%, but the lower product is marketable at a good profit. The treatment effected an extraction of 90% of all the metal of value, a most gratifying result.

Australasian Gold Production

The gold yield of Australia and New Zealand for January, as given by the *Australasian*, shows a falling off as compared with the corresponding month in 1910 and 1909. Each State in the Commonwealth has to report a decreased output, but New Zealand shows an improvement. The following is a comparison of the figures for January, including approximates for South Australia and Tasmania, with the totals for the corresponding month in 1909 and 1910:

	Jan., 1909. Fine oz.	Jan., 1910. Fine oz.	Jan., 1911. Fine oz.
Victoria	40,756	52,057	42,611
New South Wales	16,739	18,319	13,397
Queensland	24,486	29,812	24,183
Western Australia	132,286	127,350	119,497
*South Australia	780	620	1,000
*Tasmania	5,000	3,700	3,000
Total Commonwealth	220,047	231,858	203,688
New Zealand	34,318	37,868	46,067
Total	254,365	269,726	249,755

*Estimated.

Russian Copper in 1910

The quantity of copper smelted in Russia during 1910 amounted to 1,383,456 poods.* This quantity may be compared with 1,128,939 poods in the year 1909. It is an increase in production of 22%, an important one, particularly when we take into account that the production of copper in 1909 showed a considerable excess over 1908, when the production amounted to 1,031,201 poods, and still more is the contrast striking when compared with the production for 1907, which amounted to only 900,935 poods. Thus the production of copper in Russia in 1909 exceeded that of 1908 by 97,738 poods or 9.4%. That of 1908 exceeded that of 1907 by 130,266 poods or 14.4%; in the total production for 1910 as compared with 1907 we have an increase of 13 per cent.

It is useful now at the end of the year's work to give in detail the production of the various copper producing districts of Russia for the past four years.

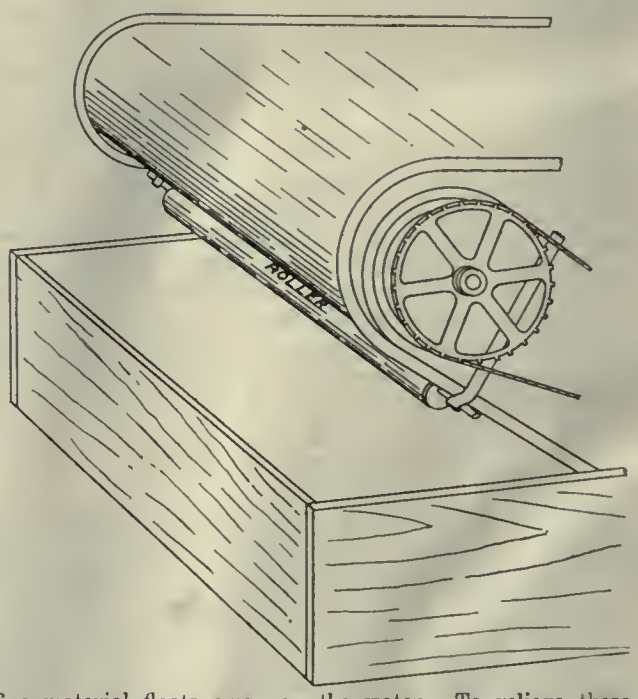
	1907. Poods.	1908. Poods.	1909. Poods.	1910. Poods.
Ural district	457,906	522,583	530,773	656,770
Caucasus	310,238	298,893	391,290	470,745
Altai	2,800	5,280	5,211	3,540
Siberia	66,157	149,829	150,582	195,900
Total	900,935	1,031,201	1,128,939	1,383,456

Lastly, we have to take account of the chemical works and refineries which can hardly be itemized, but which are probably responsible for re-smelting a large quantity of waste. These produced 63,834 poods in 1907, 54,618 in 1908, 51,084 in 1909, and 56,500 in 1910. It will be observed that the chemical works do not make much progress; this indicates that as the country progresses as a copper producer more smelters are being erected at the mines, and the chemical factories are less depended on except for handling waste and scrap. A description of some of the districts is given in the St. Petersburg letter in this issue.

*1 pood equals 36.11 pounds.

Concentrate Collecting Device

The concentrate collected by vanners is always fine-grained and usually high grade. As the belt comes to the head of the machine wash-water is run on it and the concentrate is expected to fall into the box set below. Actually much of the fine material is held on the belt by adhesion and the surface tension of the water until the first box is passed. To recover this material other boxes are placed in order and the belt dips down into water in one of them. It is necessary to scrape the material out of these boxes from time to time, and with the best care some



fine material floats away on the water. To relieve these conditions a wooden roller is sometimes placed as shown in the sketch above. By proper adjustment this can be brought up against the belt with any desired degree of tension. It operates to dry the concentrate and cause it to fall more readily into the box below. This device is in satisfactory use at a number of mines along the Mother Lode of California and elsewhere. It was invented by W. G. Dodd and first manufactured by the Union Iron Works of San Francisco, being placed on the Union concentrator. Similar devices have since been manufactured by others and may, indeed, be easily made at any mine.

Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

A PUMP designed to raise approximately 400 gal. per minute should have a suction-pipe about 9 in. diameter, delivery 12 in. diameter, and the piston 12 in. diameter.

ASSESSMENT WORK must be done on all unpatented mineral land in the United States; none is exempt. The assessment for next year can not be done the present year. If several thousand dollars worth of work be done this year it can not be applied on next year's assessment.

THORIUM MINERALS are in constant demand for use in making incandescent mantles for gas-lamps, but only one mineral that carries much thorium—monazite—has thus far been found in quantities large enough to make it commercially valuable. Some specimens of monazite contain as much as 20% of thorium, but it is generally less than 10 per cent.

MONAZITE is principally obtained from Brazil and the United States, which supply the world's demand, although the greater part of the output of the United States is used in this country. For many years North Carolina and South Carolina have furnished this supply, but important deposits have been lately discovered at several places in Idaho.

ELECTRIC SQUIBS may be used instead of electric fuses when blasting powder is the explosive used. They are made on the same principle as the electric fuse, but cost less, as a heavy paper shell replaces the copper cap of the fuse. As the charge in an electric squib does not detonate, but burns or flashes, it will not detonate dynamite or other high explosives, and can be used only with blasting powder or other low explosives.

DEGREES BEAUME, a term which is in common use among petroleum operators and refiners, is apt to be confusing to those who are not acquainted with the method by which the system of units was established. For liquids lighter than water, among which is mineral oil, the Beaumé measurements are opposite to those of specific gravity. That is to say, the greater the specific gravity of the oil, the lower the Beaumé measurement, and vice versa.

RECORDING GAUGES are used for many purposes about mines. In the dredging fields of California they are used by the Yuba company to give a continuous record of the depth at which the bucket ladder is operating. Incidentally they give a record of stoppages and delays, and allow the general superintendent to keep in close touch with the work of each dredge. Where electricity is used for power, the current-meter readings are also available and serve much the same purpose.

DUMPING rock and waste alternately from the same skip requires special arrangements at the top. At the Kennedy mine, in California, the manager, Webb Smith, has met the problem by building the rock-chutes below the ore-chutes. When rock is hoisted extra steel flanges carrying the usual curved track for engaging the skip-wheels and dumping the load, are run out over the shaft by means of a rack and screw. The skip-wheels follow the rails on these sheets and the rock is dumped in the appropriate pocket. When ore is to be hoisted these sheets are run back out of the way so that the skip travels to the higher platform before dumping.

MINING CLAIMS, in common with all patents for lands entered after August 31, 1890, or entries or claims validated by the Act of that date, are subjected to a reservation for "a right of way thereon for ditches or canals constructed by the authority of the United States." Since, however, the United States has not delegated this authority to the individual States and the right of eminent domain does not obtain against the Government, a claim held by possessory title is not subject to claims for right of way under rights granted by a State. The recent decisions of the United States Supreme Court make it clear that in all these matters the rights of the United States are supreme. After patent is passed the land becomes private property and is subject to State laws in all particulars.

ALUMINUM is used in iron and steel works for removing oxygen from the molten bath, the heat generated being so great as to raise the temperature of large bodies of iron. It also has the power of combining chemically with the gases imprisoned during the cooling of the metal, thus preventing porosity. For these purposes the metal is either used in the form of an alloy known as 'ferro-aluminum,' or as the pure metal, either in the granulated or bar form, or in small pieces weighing uniformly one-eighth or one-fourth of an ounce each. In the thermit welding process, invented by Goldschmidt, aluminum and iron oxide are intimately mixed in a finely divided state and ignited by means of a fuse. The heat of combustion of the ensuing reaction raises the temperature to the melting point. The reaction takes place in a funnel-shaped crucible, from which the fluid metal resulting from the reaction is run into a suitably shaped mold formed around the joint to be made, which is preheated by means of a blow-lamp to avoid chilling the first lot of metal coming through.

SAND-FILTERS are not properly appreciated among mill-men. They are widely used in connection with purification of water for city supplies and in certain situations may be applied advantageously in metallurgy. At the Kennedy mine sand-filters are used in the chlorination plant. The filter rests on boards raised from the bottom of the vat by one-inch wooden cubes. Above the boards is a first layer of quartz pebbles of 1 to 1½ in. diam., carefully set in place by hand. Above this and between the pebbles, is placed quartz of about ½-in. diam., and over that a layer of screened quartz of ⅛-in. size. The whole filter is about 5 in. thick. On top of the last layer of quartz, shoveling-boards are placed, being spaced about 2 in. apart. The roasted concentrate is dumped loosely on these boards. Contrary to general belief, such a filter does not become quickly clogged with slime, serving, indeed, without renewal for three months or more. The principle of the sand-filter has been applied by Bertram Hunt, W. A. Caldecott, and others, in mechanical plants, but in out-of-the-way places the simple form used at the Kennedy will often give good service.

A THREE-SHIFT system of work in a mine is rarely adopted except where time is a great consideration, as, for example, where a leasing company has only a limited period in which to operate, or where overhead expenses are unusually high. When three shifts are employed the men, at best, work only seven hours and a half to seven and three-quarters, while they always draw pay for eight hours. Three shifts also usually require one crew to follow another so quickly that the ventilation is poor and the men work at once ineffectively and under unhealthy conditions. It requires skillful management to handle three shifts effectively, though the overhead expense is thereby spread to cover more units of work. Where two shifts are employed it is customary to allow two or even four hours to intervene between one shift coming off duty and the other going on. In certain situations this is not economical. In hot countries it is bad for the men and destructive to their energy to make them dependent upon daylight hours for sleep. It is often better therefore to have the second shift follow the first promptly, so that, at worst, the men leave the mine soon after midnight and get the bulk of their sleep before day. They rest more, are better contented, and work more effectively. Such a plan necessarily involves as careful planning and as much attention to ventilation as though three shifts were employed.

Discussion

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

Western Australian Goldfields

The Editor:

Sir—As I am frequently asked about the new Western Australian goldfields by the roving and adventurous mining element—and, no doubt, there are many among your readers who would like the same information—I would suggest that a short article in your columns, stating briefly the nature and extent of the discoveries, routes, and cost of transportation from San Francisco and such other information as would be of use to one contemplating such a trip, would be appreciated. It is always quite an effort for those living remote from such news centres as San Francisco to assemble information of this kind.

PROSPECTOR.

Goldfield, Nevada, May 1.

[Australia is such a large country and conditions differ so in various parts that it is difficult to condense the information requested. However, as to steamship routes, there are three. The Union Steamship Co. of New Zealand runs an excellent line of clean comfortable boats direct from San Francisco to Wellington, with connections for Australian ports. Boats sail about every twenty days, and the time to Wellington is 22 days. From Wellington to Sydney, boats sail on Friday, arriving Tuesday. At Sydney connection is made with railways and steamships to all parts of Australia. By this route first-class fares to Sydney, Melbourne, and Fremantle are, respectively, $192, $205, and $242 one way. Second-class fares are $120, $133, and $170. Alternative routes are by way of Victoria and Canadian Pacific boats direct to Sydney or by any of the several lines from San Francisco to Honolulu, where connection may be made with boats direct to Sydney. Sailings of all these boats are announced regularly in the San Francisco papers. Details as to discovery of new districts and new mines are given regularly in our news columns, particularly in our monthly letter from Kalgoorlie. It should be remembered that Western Australia alone corresponds in size with the Great Basin and Pacific Coast portions of the United States. Much of it is unexplored. The rocks are mainly old and metamorphosed, and while men used to desert conditions in Arizona and Nevada would be at home there, they would have to unlearn and learn a great deal to prospect successfully. Extralateral rights are not recognized and titles carry leases rather than freehold. Aside from that, the mineral laws are not greatly dissimilar from our own, and they are extremely liberal throughout Australia, being designed to encourage prospecting and the influx of settlers. Fees are moderate and the States maintain helpful bureaus of information as well as geological surveys, and State stamp-mills where the prospector can have his ore tested at moderate cost. In our issue of November 24, 1910, we printed an abstract of an excellent article on the mining outlook in Western Australia, by A. Montgomery, the State Engineer. Any prospector going down there should inform himself thoroughly as to the habits and nature of camels, which in Australia are used as burros are in America. A story is told of one American prospector who neglected this precaution. However, after buying his camel and outfit he had $50 left and started bravely into the interior. The first night, in response to a question of the inn-keeper he said, "Yes, give the camel all he wants to drink." The next morning his bill was $41.50; $1.50 for his own bed and lodging and the remainder for eight buckets of water at $5 each. The expedition broke up right there, and that particular prospector came home as soon as he could earn money to pay his fare. This, however, need not discourage anyone else who is prepared to study the situation in advance and take a chance. Australia is a 'white man's country' with a low death rate, generally healthful conditions, and offers many inducements to those who have the pioneer spirit and are willing to make it their home.—EDITOR.]

Surface Indications of Ore-Shoots

The Editor:

Sir—The valuable and instructing contributions of W. H. Storms in the *Mining and Scientific Press* of October 22 are to the point. I have applied them in almost all cases of recommending or commencing of exploration and development during my mining and prospecting experience for the past 22 years. Mr. Storms' observation as to gulches, depressions, etc., crossing the strike of the vein is a rule, and the observations of others to the contrary are exceptions and only rarely occur. There is much to be learned from all of them nevertheless. But different localities present different conditions. I find in this district that wherever the percolating surface waters have access to the ore deposits for long periods, the metals disappear and are evidently carried away in solution. We miners call these cracks or fissures 'robbers,' as the occurrence of them is immediately followed by the impoverishment of the vein. Sometimes the veins or lodes are enormously rich and present all the appearance of a permanent orebody, yet upon following up the vein and never encountering a single fissure, fault, or break, the metals disappear from the gangue, neither hanging nor foot-wall carrying any ore, nor are any cross-leads to be found, but in the place of a former rich vein the same gangue still continues at its natural dip and strike, but absolutely barren. The explanation of this phase of distribution I had hoped might be brought up in the discussion. The others so far enumerated have been recognized by all miners and chloriders of any intelligence and experience. Some of the former disturbances disappear with the gaining of depth, but the latter that I have mentioned seems to me most disastrous to the miner, as it is unforseen, and in this district has never been followed out as to the final results.

So I will put the question before the mining profession as 'The Barren Zone Question and its Final Outcome in Arid Regions of the Southwest.' Kindly enlighten us chloriders and prospectors, as we are also members of the great mining fraternity and have to go first in cases of new discoveries.

LORENZ VON SCHOEN.

Fenner, California, April 14.

Re-Location v. Resumption

The Editor:

Sir—I fully agree with the statements and sentiments set forth in your editorial of April 22, under the title 'Relocation of Mining Claims,' and I am not at all in sympathy with the ideas of Messrs. J. W. Bush and E. L. Ballou, as expressed on page 565 of the same issue. The intent of the law is so clear that it seems strange than anyone should fail to understand its import. Moreover, the courts have so repeatedly passed upon this question, that there should be no further misunderstanding. To permit an original locator to hold a claim year after year without performing any work for its development or benefit in any manner is so clearly contrary to the spirit and intent of the law as to be absurd. I also think that the attempt of the California legislature to place a three-year limit to the holding of title without doing annual labor, was a mistake. It is not an improvement of the existing Federal law. Under the Federal law, should a man locate a claim on the first of June, of the present year, then, except in those States that require a specified amount of work to be performed within a given time, usually 60 or 90 days, as a part of the act of location, the locator has all of the remainder of the year 1911, and all of the year 1912, up to midnight of December 31, 1912, within which to begin the performance of the so-called annual labor. Failing to initiate this work within this time, and to continue it until not less than $100 worth has been

performed, his title, by right of location and possession, ceases upon the opening of the new year 1913, should a stranger appear at that hour to re-locate the claim, as provided by the Federal law, and the original locator has no recourse whatever.

There is a strong sentiment in some districts against this interpretation of the law. In 1905 I was in a mining camp where I had not been for many years. I noticed a cut up on the hillside 200 ft. above the village street. "Who owns that claim?" I inquired of a resident. "Jim Smith," was the reply. "How long has he owned it?" I asked. "Oh, ten or twelve years, maybe longer," was the response. "Where is his development work?" I then inquired. "There it is," he answered; "that cut up there." I laughed at him and said, "Why, that hole was made there in 1879 by Kelley; I was here myself at the time. That claim has been open to re-location for at least 25 years." He looked at me in a peculiar sort of way, and quietly remarked, with significant expression, "There's lots of claims like that in this district, and anyone coming in and attempting to re-locate any of them would find himself most unpopular—it might be more healthy somewhere else." Of course this was largely bluff, still it was an expression of the almost universal sentiment of that camp and also of many others. If the veins should be found to be rich, or for any other reason a mining excitement should begin in the district such sentiment would be quickly set aside by men as courageous and determined as these old hangers-on, and moreover the newcomers would have the right on their side, and these long idle claims would all be re-located and held by the strangers, notwithstanding the protests of the old timers. I think the Federal statutes might be amended so as to state clearly what the law contemplates in this regard. No mining district ever came into prominence through the wholesale location of claims by a few individuals who did no work on their locations.

W. H. Storms.

Berkeley, California, April 24.

The Editor:

Sir—Have read with considerable interest the articles and editorials appearing in the *Mining and Scientific Press* from time to time, and particularly those appearing in the issue of April 22 anent the right of an original locator to relocate after failure to perform the required annual labor. As the Federal Supreme Court has not as yet passed directly upon this question, and until it does, no authoritative determination of the issue, applicable equally to all of the public domain, exists, I presume the matter is still open to discussion.

As stated in your editorial, the weight of authority undoubtedly is to the effect that the location as to the original locator is not vitiated nor his title extinguished by his failure to perform the annual labor, but that the same endures until extinguished by the initiation of a hostile claim by others; and that in the absence of such hostile claim, the original locator may resume work at any time with the same effect as though no failure had occurred. From this, it would logically follow, that in the absence of such hostile claim the location, so far as the original locator is concerned, is still a valid and subsisting claim, and one upon which he could not make a valid re-location. It could hardly be contended that the attempted re-location, *ipso facto*, constituted an abandonment of the original location, and if it did not, the attempted re-location, as stated in your editorial, is the best evidence that there never was a real abandonment or intent to abandon, and consequent extinguishment of the original location irrespective of the performance of the annual labor, and it is a well settled rule of law that no person will be permitted to take advantage of his own fraud.

But aside from these technical considerations of the case, the manifest intent of Congress in prescribing the annual labor requirement was to prevent speculators from perpetually monopolizing the public domain to the exclusion of bona fide locators, and the retardation of the development of our natural resources. To permit a speculator to hold his ground and exclude genuine locators merely by relocating year after year, would be so palpable an evasion of the reason and spirit of the law as to be unworthy of serious consideration. In the construction of statutes it is a well established rule of law that "Of every legislative act intelligent purpose can be predicated, and the end contemplated by that act and toward which it was directed by the legislative power, must always be considered in determining the character of the act itself; and when, under one interpretation the effects and consequences are absurd, unjust, or contrary to the public good, and under another interpretation such effects and consequences are reasonable and just, it is evident that the latter interpretation is alone correct."

I am sorry that the company by whom I am employed does not consider a good law library a necessary adjunct to the operation of a mine, or I might be able to cite some recent decisions bearing upon this important question.

C. W. L. Stevens.

Goldfield, Nevada, May 5.

The Editor:

Sir—Just what the makers of the law of 1872 intended in relation to allowing a claimant to re-locate as well as resume work to continue lawful possession of mining ground, might be made clearer by referring to the *Congressional Record* of that time. In the absence of this, the apparent absence of any court decision in the matter, and the custom of many years, makes it look, on the face of it, as though re-location is not prohibited, or that it opens a claim contest. That claim-holders are any more prone to strive for 'something for nothing' than men in other walks of life will hardly be asserted. The claim-holder looks at re-location as a question of choice on his part. When the last minute arrives he may maintain the title he already has by resuming work, or he may abandon what work he has done and acquire a new title by re-location. That abandonment preceding re-location is genuine appears when patent is applied for, the $500 worth of work having to show for the final location. A careful reading of the excellent special act for Alaska shows it can be readily interpreted to mean that in all other sections the claim-holder can himself re-locate his former ground. It would be no less fair to claim its sanction by Congress in the special Act of 1891 in relation to the Uncompahgre Indian lands, wherein the perfection of certain titles is contingent on re-location.

As far as getting the country prospected goes, it really is immaterial whether one man holds the ground without work, or whether a succession of locators hold it in like manner. Until $500 is expended a patent is not possible, and there are many chances of trouble for the claim-holder who fails to do his annual work.

E. L. Ballou.

Igo, California, May 6.

Uses of Manganese

The principal use of manganese ores, according to E. C. Harder of the U. S. Geological Survey, is in the manufacture of iron-manganese alloys such as spiegeleisen, ferromanganese, silverspiegel, and silicomanganese. The first two of these contain principally iron and manganese; the last two contain considerable silicon in addition. Ferromanganese and spiegeleisen are used in steel manufacture as reducers of iron oxide during the final melting, as recarburizers, and in the manufacture of special steels alone or in combination with chromium, nickel, tungsten, and other steel-hardening metals. Manganese is also used in the formation of alloys with copper, aluminum, zinc, tin, and other metals. Manganese ores or manganiferous iron ores are used to a slight extent as fluxes in the reduction of silver, lead, and copper ores. Manganese peroxide is used as an oxidizer in the manufacture of chlorine, bromine, and oxygen, and of potassium ferromanganate; as a drier in paints and varnishes; as a decolorizer of glass; and in the manufacture of the dry and the Leclanche cells.

Special Correspondence

ST. PETERSBURG, RUSSIA

ALTAI COPPER PRODUCTION.—FUTURE OF ALTAI INDUSTRY.—URAL PRODUCTION.—BOGOSLOFF AND KYSHTIM.—INCREASE OF PRODUCTION AND CONSUMPTION.

The smelting of copper at Altai (in the Suzunsky factory) is effected under the disadvantageous circumstances of absence of means of communication, resulting, of course, in a restricted development of the industries of the district, and it is further to be observed that the exploitation of the copper deposits up till now in that neighborhood can not be called active. The complexity of the Altai ore and the resistance it offers to treatment are hardly equaled the world over; and therefore at the present moment the smelting of copper at Altai may be considered only a survival of the past importance of the country as a mining centre.

Its future is by no means in doubt, though for the moment the Altai copper industry is quite insignificant, the production not only is not increasing, but the tendency is rather to decrease. The reasons for this are on the one hand the poorly developed condition of Russian chemistry, particularly in the handling of pyrite and also the rapid development of the metallurgical production of the red metal on the copper ore producing fields. If on the basis of the figures given on page 728, we consider the proportion of the increase in the production of copper-bearing districts in 1910, compared with 1907, we find that the Ural production has increased by 43.4%; that of the Caucasus 51.1, and that of Siberia by 206.8. Consequently, above all, the increase in the production of copper is most observable in the Siberian factories (Spassky, Yenissei, and the Dzhiltaffsky). This, of course, is quite comprehensible, because all these factories began production only at the beginning of the present century. In their case it is rather the birth of the production of copper and not the development of the industry that is to be considered. After the Siberian factories follow the Caucasus, where for the last few years the development of the copper industry has been rapid and extensive, particularly in the case of the Alaverdesky factory and the Caucasian Copper Co. and the Dzansulsky factory.

In the Urals the largest producing works is the factory of the Bogosloff, following which is the factory of the Demidoff's Successors. Independent of the activity of these producers of copper there is the Kyshtim company, which has had a considerable share in the Urals' output. This company produced 93,747 poods in the year 1910, against 17,502 poods only obtained at its works in the year 1907.

The foregoing confirms the estimates that have been made from time to time in the course of the year 1910 respecting the probable results of the copper companies' operations. It need only be briefly stated, in order to avoid repetition, that the copper situation in Russia is one calculated to give pause to other copper producing countries that have acquired the habit of looking to that land as a good and lasting market. The development last year indicates that within a brief period the country will be self-supporting in copper, and the only advantage that outsiders will have will be the cost of carriage from the great copper-producing centres of the Urals and Siberia to industrial districts near the ports, where water-carried copper has an advantage. But against this has to be set the enormous progress that has been made by the Caucasus, and there is no indication either here or in the other areas named—the Urals and Siberia—that either the source of supply will fail to respond to increased calls or that the production of the finished article is likely to be carried on with diminished intensity. Consequently the Caucasus must in self-defence, so to speak, become an exporter of metallic copper, and it will be a simple matter for the Russian Government to consider Caucasian copper shipped, say at Poti, Novorossiisk, or Taupse, to the South Russian ports in the Black Sea, or to the Baltic ports, in Russian bottoms, as not having left the country and consequently as standing free of import duty; so that Russian produced copper can be delivered by water carriage on the same terms, as far as freight is concerned, as other countries' copper; and enjoy the while the tariff protection. The industries of Russia are developing with great rapidity, and machinery requiring copper, including sugar-mills, cables, electric works at mines, and others, is being called for in ever-increasing quantities, so that after all the rising tide of home production may not fill the widening gulf of home consumption.

BLACK HILLS, SOUTH DAKOTA

DEVELOPMENT OF DUNN PROPERTIES.—CONSOLIDATION OF PORTLAND PROPERTIES.—SALE OF HIDDEN FORTUNE IS POSTPONED.—SALE OF THE ALDER CREEK.—DIVIDENDS FROM WASP NO. 2.—DREDGING NEAR MYSTIC.

The Deadwood Lead & Zinc Co. is the name of a new corporation, organized locally, to develop the Dunn properties on Spruce gulch, near Deadwood. Aaron Dunn is president and O. N. Brown general manager. A large body of ore carrying pyrite, zincblende, and galena is exposed in the workings. A carload has been shipped to the Safe Investment mill. The middling, containing the iron and zinc, will be shipped to Plattesville, Wis., where it will be treated by the Huff electrostatic process. The ore carries gold and silver, averaging $3 per ton, 5% galena, and 4% zinc.

The Trojan Mining Co. has been incorporated to consolidate the interests of the Portland, Clinton, and American Eagle companies, in the Portland section of the Bald mountain district. This gives the company 700 acres of mineral land, with a large amount of known ore. The American Eagle mill is being remodeled by moving the crusher from the top of the building to a convenient location beneath new ore-bins on the hill at the rear of the plant. A belt-conveyor will take the crushed ore to the mill-bins. Additional Dorr classifiers are being installed, a Dorr pulp-thickener and a stationary-leaf slime-filter. The plant will have a capacity of 300 tons per day. Electric haulage will bring all ore to the mill through tunnels and sheds. H. S. Vincent, of Deadwood, is general manager.

Sheriff's sale of the Hidden Fortune property has been postponed to July 8, upon representation of stockholders that a deal was on foot which would result in work being undertaken and all obligations met. The mines of the Black Hills Development & Financial Corporation, at Carbonate, are being developed to produce a weekly tonnage of 200 tons of gold ore from the Seabury-Calkins, and 100 tons per week of silver ore from the Iron Hill. Shipment is to commence soon. The Alder Creek property has been taken over by Illinois interests, and the cyanide-plant will be overhauled and electric equipment added.

Development work has been suspended by the Imperial company in the shaft at the head of Annie creek. The burning out of a motor in the station at the bottom of the shaft damaged the station and stopped the ventilating apparatus. Repairs will be made and work resumed shortly. P. H. Bertschy, who is leasing at another point on the Imperial territory, is making regular shipments to the Lundberg, Dorr & Wilson mill at Terry. Delay has been experienced at the Reliance in getting things in shape for starting the mill. One of the slowest tasks to finish is that of soaking up the tanks and making them water-tight. Twenty stamps furnished by the Stearns-Roger company, of Denver, have been erected in place of Chilean mills, and other minor repairs made.

Wasp No. 2, on May 1, declared its first dividend since the rebuilding of its mill, which was destroyed by fire in January 1910. The new plant was started in December. The plant is treating 500 tons per day, and the average bullion recovery is $2 per ton. Mining and cyaniding costs are less than $1 per ton. It is expected that the Castle Creek company's dredge, near Mystic, will be in operation before June 15, as it is practically completed. Another dredge is to be put in farther down the stream, J. Charles Sherman, of Pactola, having charge of this latter concern.

SALT LAKE, UTAH

SMELTER WINS SMOKE DAMAGE SUIT.—GOOD ORE AT ALTA.—UTAH SILVER PRODUCTION.—NOTES OF PROGRESS.—INCREASED PRODUCTION AT UTAH CON.—NEW LEAD FURNACES.

The U. S. S. R. & M. Co. has won the last of the smoke-damage suits brought against it, the jury, in the suit of Walter Steadman for $14,000 damages for death of sheep, bringing in a verdict for the company. The Sierra Nevada Prospecting Co., which sent out E. B. Learned to locate claims, has received a report that he has located some claims at Rose Springs from which rock has been sent in running $12 to $178 in gold. The roads to Alta have cleared of snow, and the mines of that camp are beginning to ship. The recent discovery in the Utah Mines Coalition at Alta has broadened into 8 ft. of shipping ore. The International Smelting company is handling more copper ore than ever before at its Tooele plant, the average running from 600 to 700 tons per day. The regular 2% quarterly dividend is promised this month. According to a circular from the U. S. Geological Survey, Utah was second in silver production in 1909, with a record of 10,551,100 oz., second in amount of ore treated with 5,119,325 tons, and sixth in gold production, with 203,818 oz. The Burro mine in City Creek canyon, within ten miles of Salt Lake City, will begin shipping ore this month. The Columbus Extension in the Alta district will extend its main tunnel 800 ft. farther to a point under the old Toledo shaft. The Utah Metals tunnel in Bingham is now in 5000 ft., or about half way through the mountain. Two shifts are averaging 5 to 6 ft. per day, at a cost of $11 per foot. The old Maxfield Mining Co., operating in the Big Cottonwood district, has changed its name to the Salt Lake Power & Mining Company.

By reason of improved conditions in the lower levels of the Utah Consolidated, that company has been able to increase its shipments to the Tooele smelter, that now amount to 500 tons of ore daily. The increased tonnage is due to the development which has been in progress during the last four months below the main haulage-level. The Tooele plant of the International S. & R. Co. is treating 700 to 800 tons of copper ore per day. Many contracts with operators for lead ores have been made by this company, and it has been decided that the two lead furnaces being built shall have the capacity of 500 tons each, instead of 250 tons, as originally planned.

GLOBE, ARIZONA

THE OLD DOMINION TO INCREASE MILL CAPACITY.—MIAMI MINE AND MILL.—ARIZONA COMMERCIAL.—INSPIRATION.—SUMMIT AND WARRIOR.

It is learned that the Old Dominion Mining & Smelting Co. has decided to add a 500-ton unit to its concentrator because of the existence of large bodies of concentrating ore in the United Globe ground. Plans for this addition are not yet perfected, but a set of 13 by 16-in. rolls and a 6-ft. Chilean mill are now being erected. During April the Old Dominion company concentrated 11,085 tons of ore and smelted 29,275 tons of charge. Its production for the month was 2,515,000 lb. of copper. The electric locomotive that was started on the fourteenth level in March has proved so satisfactory that another locomotive of the same type and size is to be put in use on the sixteenth level. The Kingdon shaft is now about 360 ft. deep. Sinking on 'A' shaft (the main shaft) has been begun. It will be sunk to the depth of 1800 ft. The new 'high line' connection with the Arizona Eastern road's main track will soon be completed. It will reduce the grade from 4% maximum to 2.8% maximum, and will be in operation by July. A shed is being built over the ore-bins at the smelter; a perfect mixing system direct in the bins will be completed by June 1.

The Miami mine and mill are working satisfactorily, although the mill is running at but half capacity because of the unfinished state of units 4, 5, and 6. The rest of the equipment of unit No. 4 will soon be ready, but it will be some time before the other two units will be operating. The three now in operation are handling 1500 tons of ore daily. The metal recovery at the mill is 75%, a saving the management expects to increase. The concentrate is averaging above 40% copper, which probably will be increased to 42% in the near future, and allowing for a loss of 2% at the smelter, there will be a net saving of 40%. The caving system is only advanced to the extent that light sets have been erected between the capping and the orebody. When the stopes and pillars recede as the ore is drawn out, these timbers will fall or be shot down, thus forming a mat of timber between the receding ore and the settling cap. The Miami company now employs about 500 men.

The Arizona Commercial cross-cut north from the 1000-ft. station has extended through the Black Hawk vein, 35 ft. in width, and is continuing north to explore the Old Dominion fault. The vein shows heavy mineral impregnation, but because it is badly broken where cut, it is impossible yet to get an assay that would give an average value. A drift is being run along the foot-wall of the vein, and cross-cuts will be cut through the vein at intervals. Copper glance ore running almost 80% was

MIAMI PORTION OF GLOBE DISTRICT.

cut by the winze below the seventh level. The ore was found where the diamond-drill had penetrated the glance, 90 ft. from the collar of the winze. The ore will not be developed until the winze has been sunk to the 800-ft. level. The shaft is now about 1100 ft. deep and is sinking at the rate of 2 ft. per day through the hard diabase. At the Superior & Boston excellent ore has been uncovered 35 ft. southwest from the south station of the 1000-ft. level. The ore is heavy in iron and contains glance, chalcopyrite, specks of cuprite, and silver. It is 20 ft. wide where found. The Great Eastern vein (which contains the ore) was missed in the development work for the past two months because of the increase in the dip of the vein. The Great Eastern vein is identical with the Black Hawk vein of the Arizona Commercial; and in all the workings above the 1000-ft. level in both properties the vein has dipped north at an angle of about 47°. The Superior & Boston management went far enough north to cut the vein at its supposed dip before driving westward to catch it. The revelation in the A. C. a few days ago of the abrupt 'straightening up' of the vein at the 1000-ft. level, led the other mine's management to abandon the west drift and start another southwest from the shaft. It caught the ore in 35 ft. The Live Oak's new shaft (No. 2.), being sunk by McIvors brothers and Ross, who made the best record for one week that has been made in the district, now has a depth of over 200 ft. Work preparatory to blocking out ore is in progress at the old shaft. Four drills are being operated on the property.

The Inspiration company has received its generator,

electric locomotives, and much of the underground haulage-equipment. The rails in the levels are being bonded and the wires are being strung. With exception of a drift to the east from the Colorado shaft at the 500-ft. (3350 ft. above sea-level) level there is not much underground work being done at the property, everything awaiting the building of the power-plant. Four drills are in use. The Summit company still finds high-grade ore on the 400-ft. level south, having cut it again in the vein sooner than expected from its features on the upper levels. The cross-cut being driven to the west to cut the Pasquale vein is about 300 ft. from the station. It has passed through the Intermediate vein. The vein is so small that it is improbable the company will develop it. No ore is being taken from the mine except such as is broken during development. The Warrior Development Company continues to ship from 100 to 125 tons of 10% chrysocolla daily to the El Paso smelter. Considerable development work is being done, and a churn-drill is being operated on the western part of the Warrior group. The German Copper Co. has been organized and will start work on its ground 2 miles north of Globe. The Manitou Copper Co. is an organization that has taken over the Five Points and Manitou properties about 8 miles west of Miami. Work on a 500-ft. shaft on the former group will be begun at once, a hoist will be erected, a pump installed, bunk-houses, blacksmith-shop, and carpenter-shop built.

EASTERN OREGON

BEN HARRISON MINE.—CORNUCOPIA MINES CO.—GOOD SHOWING ON THE GORMAN.—MORNING AND RED BOY.—SALE OF MORMON BOY.

The Ben Harrison, situated on Clear creek in the Greenhorn district, Grant county, was recently purchased by Ohio investors, headed by A. L. White, president of the Lima Locomotive & Machine Co. Air-compressors, Leyner drills, and other appliances for effective work have been provided, and about 50 men are on the payroll. The mine has ore-bodies from 12 to 15 ft. wide, the ore assaying from $15 to $20 per ton. W. C. Fellows is in charge.

The Cornucopia Mines Co. owns 41 quartz claims, 22 of which are patented, all situated at Cornucopia, Baker county. The shipping point is Robinette, on the Northwest railroad, 25 miles from the mines. The mines produced steadily for a number of years under the ownership of the late John C. Searles, and have recently come into the possession of Benjamin B. Lawrence and associates, of New York, who intend to add a new mill and cyanide plant. Two-fifths of the mine product is free-gold ore, which, with some concentrate, runs from $150 to $200 per ton. Several carloads are now in transit to the Oregon-Idaho sampling works at Baker. Present equipment includes a 20-stamp mill operated by electric power. About 70 men are employed. Robert M. Betts is manager.

The Gorman adjoins the Humboldt on the east end and covers the same vein that is opened in the Rainbow and Humboldt. The wash is deep on this group, and the biggest showing of quartz float to be found in the Northwest is strewn over the surface, some of the boulders weighing two tons. For years people have been hauling away this float to near-by mills and arrastres and treating it at a profit. Spokane people have become interested in the Gorman, and a force of men is now at work to open the vein. The adit is in 500 ft. and by driving 200 ft. farther the vein will be opened.

The Morning group of 10 claims has been bonded and is being developed by Frank E. Pearce, formerly superintendent of the Iron Dyke mines. The property is situated 9 miles from Austin, on the Sumpter Valley railway, in Grant county. The property is equipped with a 5-ft. Bryan mill, and concentrators. Ore 20 ft. wide can be mined and milled at a profit, and some shipping ore is in sight. Over 4000 ft. of work was done in the past, but the new work, under Mr. Pearce's direction, shows better results.

The Red Boy, which has been inactive for several years, is now owned by Ray Nye and associates, of Fremont, Nebraska. Mr. Nye arrived at Baker recently for the purpose of re-opening this property, and is arranging to sink 500 ft. below the present lowest level. The mine was formerly a dividend-payer. The location is near Granite, Grant county, 18 miles from Sumpter. It is equipped with a 20-stamp mill, hoisting machinery, air-compressors, and electric power. An ample development fund has been provided by the owners to carry out their plans. John Farrell is in charge.

The Mormon Boy group, in the Cable Cove district, near Sumpter, has been taken over by Sidney C. Love of New York, who is giving the development work his personal attention. The mine has a 3-ft. orebody; 2 ft. of this is of milling grade, and 1 ft., next to the foot-wall, is shipping ore. A cross-cut, 200 ft. below the old workings, is being driven, by which the vein will be reached at 175 ft. from the portal. Fifty tons of $115 ore is now piled up on the dump, and this will be forwarded to the Oregon-Idaho sampling works at Baker.

MEXICO

NO BULLION TO BE HANDLED BY MEXICAN NAT. RAILWAYS.—FEDERALS IN AGUA PRIETA.—CONDITIONS ON WEST COAST.—END OF TEZIUTLAN COPPER CO. SUIT.—MOCTEZUMA DAM.—MINING IN OAXACA.

A recent general order of the Mexican National Express Co. against the acceptance of money or bullion for shipment is affecting mining companies in Mexico. The order is expected to continue in effect until all danger of loss at the hands of revolutionists or bandits is past. Considering the unsettled conditions and traffic interruptions, shipments of ores and bullion over the National Railways of Mexico have been well maintained up to this time. So far the greater part of the decrease in earnings of the system has been chargeable to the falling off in passenger receipts. Ore, bullion, and oil shipments constitute over one-fourth of the total freight handled by the National Railways. The taking of Juarez by the revolutionists was followed by the announcement that the repair and operation of the Mexico Northwestern line would be permitted. This is important to some of the mines of western Chihuahua. As a result of the fighting around Agua Prieta, no trains were operated for nine days over the Nacozari railroad, which handles the shipments of the Moctezuma Copper Co., the Lucky Tiger Gold Mining Co., and other mines. The recent abandonment of Agua Prieta by the Federals caused apprehension among the companies using the Nacozari railroad, as it left them without customs facilities. However, the revolutionists have occupied Agua Prieta, and it is stated that they will handle customs affairs there, as they are doing at Juarez. Cananea was recently surrendered to the revolutionists, but the rebel occupation has not interfered with the operations of the Cananea Consolidated Copper Co. There is little fear of interruption there, unless rail communication with the United States is cut, shutting off fuel-oil supplies. If the port of Naco, also abandoned by the Federals, remains closed, all Cananea shipments will have to be handled through Nogales. A number of Southern Pacific bridges in Sonora and Sinaloa have been destroyed, and traffic is demoralized. The revolutionary activity in Sinaloa has greatly curtailed mining operations in that State. Mazatlan, the principal Sinaloa seaport, is under siege. Durango is without railroad service. Levies have been made on foreign as well as Mexican mining companies by armed bands, some of them posing as revolutionists, and others as bandits. Revolutionists have entered Pachuca, but there has been no attempt to interfere with operations in that district. Operations in the important El Oro district have continued without interruption. Disturbed conditions have affected mining to some extent in the Taxco district of Guerrero and the Zacualpan district of Mexico.

A Federal court decision, confirmed by the Supreme Court of Mexico, has lifted the embargo on the Teziutlan Copper Co., resulting from a judgment rendered last June. This

judgment was for ₱23,059,084 in favor of the Compañia Explotadora Mexicana, of Mexico City, against George D. Barron, at one time prominently identified with the Teziutlan enterprise. It disclosed the fact that the case had been in the courts since 1900. The Compañia Explotadora was organized in 1895 by men well known in Mexico, the object being to acquire and develop mines in the Teziutlan district of the State of Puebla, and Mr. Barron was elected president and general manager. The case against Barron was based on the allegation that the company authorized him to acquire the Aurora and other mines, which have since become big copper producers, and that, instead, he took titles in his own name and later transferred the mines to the Robt. S. Towne interests, which control the Teziutlan company.

The Moctezuma Copper Co., the Phelps-Dodge concern operating in Sonora, is building a dam to hold storm-water for use at its 2000-ton mill at Nacozari. Scarcity of water at the end of the long dry season each year has forced the company to curtail operations. It is believed that the storm-water gathered will be sufficient to give the mill an adequate supply throughout the year. The production of the Moctezuma company in the first quarter of the year was 5,738,054 lb. of copper, as against 5,852,608 lb. in the

THE NATIVIDAD MILL, SIERRA JUAREZ, OAXACA, MEXICO.

first three months of 1910, and 6,500,583 lb. in the same period of 1909.

In spite of conditions prevailing in several regions of the country, mining in Oaxaca seems to improve a good deal, owing to the fact that in some of the operating mines workable orebodies have been found recently. Among the mines that are now in good shape is the Natividad mine, a Mexican company situated in Sierra Juarez, 36 miles north of the city of Oaxaca. This mine is in an old mining camp of somewhat complicated geological structure composed of black slate and limestone cut by several instrusive bodies and dikes, the former much eroded. In the Natividad mine there are three parallel veins near each other, two of them large (from 4 to 12 ft.), and the other a narrow but sometimes very rich one. The three are flat veins dipping to the west, while their strike is north-south.

The veins have a brecciated structure and are composed of quartz and pieces of slate or porphyry through which are disseminated the metallic minerals, mainly gold, a little silver, and variable amounts, though always abundant, of zinchlende and galena. Iron pyrite is present always in the veins and is associated with the gold. The ores occur in pockets of variable size, but large enough to pay big profits when a pocket is found. The mine has at present two orebodies in hand, and the ores left in the old workings are also worked. The Natividad company has a 70-ton cyanide plant that may be increased to 100 tons when the new power plant is finished. With the new ditch at present being constructed, a head of 600 ft. is obtained and 800 hp. will be developed. The mill has 30 stamps, two tube-mills, and employs Pachuca tanks with a modified method of agitation. Owing to the character of the gold and especially the silver, recovery is not very high, but the company expects to obtain better results by improving the concentration.

This company has not paid dividends for several years, but there is every prospect that it may pay some in the near future. Well informed people say that the ore actually developed represents a gross value of ₱1,500,000. The Sierra Juarez is a country magnificently carved by erosion, with deep *barrancas* and steep mountains, while big blocks have been displaced by faults. The old carving work has been refilled with more recent volcanic overflows, mainly of andesitic character, cut again by younger active erosion.

GOLDFIELD, NEVADA

April Report Goldfield Con. M. Company

In his report for April, J. F. Thorn, general superintendent, gives the following figures:

During the month of April, the total production of the company was 28,253 tons containing $1,061,496, or an average extraction of $35.75 per ton, or 95.16%. The total net profit to the company was $796,151, or $28.18 per ton. The development work amounted to 3961 feet.

The total cost of mining, development, transportation, milling, office and general expense was $7.68 per ton, distributed as follows:

Mining:		
Development	$1.11	
Stoping	2.21	
		$3.32
Transportation		0.09
Milling		2.22
Marketing		1.10
General expense		0.37
Bullion tax		0.52
Construction		0.06
Total cost of operation		$7.68

During the month 330 tons of ore was mined from the sill-floor of the 136 stope on the second level of the Combination mine that averaged $200 per ton. Another orebody was found 50 ft. west of the 136 stope that will probably connect up with the main stope, making a stope 75 ft. long and 10 to 15 ft. wide.

In the Mohawk mine the 260 sill-floor on the second level, and the 354 sill-floor on the third level were considerably extended. One thousand two hundred and twenty-three tons of ore that averaged $30 per ton was mined from the 354 sill. The 384 and 385 drifts, on the third level, on the foot-wall of the 354 stope were extended 100 ft. through ore that averaged $20 per ton. The foot-wall was not exposed, but the indications are that the orebody will be about 10 ft. wide, and is now opened up 200 ft. in length; the face of the south drift still being in ore.

In the Clermont a winze is being sunk through the 604 orebody to connect with a raise from the 1200-ft. level of the Grizzly Bear. The winze was started in the hanging wall of the orebody and was rather low grade, but it is now down 50 ft. (on the incline) and is averaging $50 per ton. It is hoped to have the raise and winze connected about the first of June, and will then have good air and can rush development work on the 1200-ft. level. Two hanging wall cross-cuts are being driven on this level (one north and one south of the Grizzly Bear shaft) and the quartz mass is wider and stronger than on the 1000-ft. level of the Clermont. The 700-C hanging wall raise, which is practically a cross-cut on the 1200-ft. level 200 ft. south of the shaft, cut six or seven feet of ore that averaged $12 per ton. The air on this level has been very bad, and until the winze and raise are connected it will not be possible to do much work on this orebody. The mines as a whole are looking well, and are producing about 940 tons per day, which is all being treated at the mill.

General Mining News

ALASKA

W. H. Parsons, of the Dexter-Horton National Bank of Seattle, estimates an output of $10,000,000 in gold from the interior camps of Alaska this season, including Fairbanks, the Koyukuk, and Iditarod.

Juneau District

The report of the Alaska Treadwell Gold M. Co. for the month ended April 15, 1911, shows 31,416 tons of ore crushed in the 240-stamp mill, and 20,636 tons in the 300-stamp mill, a total of 52,052 tons. In the former mill 600 tons of concentrate was saved, in the latter 407 tons. Estimated gross value of free gold recovered, $68,187.67; estimated gross value of concentrate, $42,239.88; total, $110,427.53. Estimated realizable value, $105,987.76; operating expenses, $95,889.98, leaving an operating profit of $10,097.78. Construction expenses, $10,013.11. Yield of ore milled, $2.12 per ton. Stock of ore broken, 20,911 tons; development work, 198 ft. in ore, 576 ft. in waste.

Prince William Sound

A. Von Gunther has purchased from Arthur Zilberman an interest in the Ground Cliff group of mining claims, situated near Valdez. A 7-ft. vein contains a good grade of gold ore. The Glacier group, situated at the head of Mineral creek, was sold to A. G. Brown and M. S. Griffith. Assays of surface ore across an 8-ft. vein are said to have shown $28 per ton.

ARIZONA

Mohave County

The Needles Mining & Smelting Co. is erecting a 2-mile aerial tramway, Trenton Iron Co. system, from the Banner mines to the foot of Stockton hill. It is stated by the *Miner,* published at Kingman, that the Santa Fé company is to build an 8-mile railroad branch from Berry station, 6 miles east of Kingman, to the lower terminal of the tramway for the haulage of ore mined in the Stockton hill camp, where the Needles M. & S. Co. has done a great deal of development.

The Tom Reed Gold Mines Co. recently made a clean-up of gold and silver bullion worth $76,500, as the result of 30 days run of its 20-stamp mill, and this is the largest product for any month since the mill was started.

The following data, taken from reports of mining companies to the county assessor, show the output of various mines of this county for the year ended May 1, 1911: Gold Road, $603,262 in gold, $6992 in silver; Tom Reed, $484,717 in gold, $5822 in silver; Needles M. & S. Co., $2007 in gold, $1419 in silver, 134,258 lb. lead, 95,844 lb. zinc; Golconda, $15,447 in silver, $18,189 in gold, 6,038,574 lb. zinc, 32,634 lb. lead; C. O. D., $14,268 in silver, $2666 in gold, 26,049 lb. lead; Adams lode, $1504 in silver, 4895 lb. copper. Totals: Value of gold and silver, $1,156,279; zinc, 6,134,418 lb.; lead, 192,941 lb.; copper, 4895 pounds.

Rich gold ore has been found in the low hills near Boundary cone, half way between Gold Road and Needles. The ore comprises quartz, containing free gold and oxidized iron.

Pima County

The Mines Company of America, which controls the Silverbell, Tombstone, Saddle Mountain, and other mines, also the smelter at Sasco, is reported as having decided to blow-in the furnaces of the Sasco plant to treat ore from the Saddle Mountain mine, situated at Christmas, in Gila county. Recent development in this mine of massive bodies of copper ore is said to be such as to assure a tonnage sufficient to keep the plant in operation. A considerable percentage of this ore is sulphide. Winkelman is the nearest shipping place, and this is close to Hayden, where the Ray Con. smelter is being built.

Pinal County

Two sections of the concentrating mill of the Ray Consolidated, situated at Hayden, on the Gila river, are treating over 2000 tons of ore daily, and it has been demonstrated that each section has the capacity to concentrate 1200 tons per day. The third section probably is in operation by now. Five more sections of similar capacity are under construction; the eight sections, when all are complete and in operation, are expected to treat close to 10,000 tons of ore per day.

CALIFORNIA

Amador County

The 40-stamp mill of the Bunker Hill company operated 26 days in April, mostly on ore taken from the 1950-ft. level. The bullion output for the month amounted to $27,000. It is claimed the vein has considerably widened at 1950 ft. depth.

The Central Eureka's 40-stamp mill was put in operation April 2, on ore of good grade that is being mined on the 1500, 2700, and 2800-ft. levels. This mine was profitably operated from 1900 to 1906, and was closed down in 1908, when the orebody was found to have pinched at the 2500-ft. level. Some time later than this an orebody corresponding to that of Central Eureka was found below the 2500-ft. level on the South Eureka, which led to the opening of the big reserves of ore now being mined on the 2700 and 2800-ft. levels of the Central Eureka. This important work has been performed under the superintendency of James Davis. The property is on Sutter hill, between Jackson and Sutter Creek.

Butte County

The Burlington Gold M. Co., having four patented claims close to Forbestown, has put in a gasoline hoist, and is letting a contract for 100 ft. of driving; the intention is to sink a shaft. The object of this proposed development is to be able to further define the ore-shoot found in the north-south vein on which a 435-ft. adit has been driven. The latter work shows the vein to be 4 ft. wide. Assays of a number of samples show an average of about $8 per ton.

Calaveras County

The Lightner Gold M. Co. started 20 stamps in its 60-stamp mill on May 15, and expects soon to have all stamps in operation. The new shaft, sunk during last winter, has a depth of 425 ft. Cross-cuts are being driven to the vein

NEW SHAFT, LIGHTNER MINE.

from the 300 and 400-ft. stations; the cross-cut from the 200-ft. station has been finished. The old shaft, 255 ft. from the new one, is used for taking timbers into the mine. The ore runs about $4 per ton. A new 250-hp. electric hoist has been put in use at the new shaft. The air-compressors are also electrically operated. The Lightner Gold M. Co. purchased the property from the old Lightner M. Co., and the litigation, recently mentioned, is between the old company and J. D. Coleman, and does not concern the Lightner Gold M. Co., which has undisputed control of the property. The operations are superintended by Bayles C. Clark, formerly of the South Eureka mine; J. R. Farrell, of San Francisco, is consulting engineer. The property is at Angels Camp.

The Melones Mining Co. mined and milled 148,900 tons of ore for the year ended October 1, 1910, at a total cost of $1.08 per ton. This mine, situated at Carson Hill, was

opened in 1895, after Eastern investors had become interested through the efforts of W. C. Ralston. The ore is worked by the shrinkage system and there are stopes 30 ft. wide by 350 long. The mill has 100 stamps, by which an average of 4.41 tons per stamp was crushed during the year named. The ore milled yielded $1.98 per ton, 42% of which was recovered by amalgamation, 58% by concentration. The extraction was 88%. The property is equipped for operating by both electric and water-power. W. G. Devereux is manager.

Inyo County

The Keane Wonder M. Co. has given George Wingfield an option on its mine and mill, situated on the west slope of Funeral range, facing Death valley, about 20 miles southwest of Rhyolite, Nevada. The mine has been under examination by F. J. Siebert for Mr. Wingfield. Homer Wilson, one of the stockholders, has had the management of the property, and two years ago built a 20-stamp mill and cyanide plant, since the completion of which 27,000 tons of ore, averaging about $12 per ton, has been treated.

Kern County

A small tonnage of ore taken from the King Solomon mine, Randsburg district, milled $240 per ton by amalgamation. Sinking on the property is in progress, and drifts on the vein are driven from the 50-ft. station. The property belongs to J. J. Miller. It contains the extension of the Butte lode.

Nevada County

(Special Correspondence.)—The Coan Mining Co. has begun operations, the results of which indicate that its property is developing into one of the good mines of the county. The 10-stamp mill is proving the ore to be similar to that of the other mines along the same lode, such as the Champion and Spanish. Ten men are employed. Dan McDonigal, formerly of Alleghany, is manager. The Pittsburg 20-stamp mill is working with two shifts on ore taken from the 1300-ft. level. M. B. Kerr is manager. At the Champion mill 20 stamps are dropping on good ore. It is stated that the North Star Mining Co. expects to take over the Champion group.

Nevada City, May 16.

The Arctic group of 12 claims, belonging to Ole Helgeson and Martin Van Berg, and situated on Canyon creek, 7 miles east of Washington, has been leased and bonded to J. P. Flint and associates. The claims cover a mineralized zone, said to contain seven parallel veins of gold ore in granite. Canyon creek cuts through the vein system at right angles, exposing the formation and making it possible to open the veins at a depth of 1000 to 1500 ft. by adit-levels. It is announced that a mill for amalgamation, concentration, and cyanidation, to be equipped for treating 250 tons of ore per day, is to be built at the mine this season, and that the plans are made and that orders for the machinery have been placed. The ore-dressing is to be done by crushers, rolls, and conical pulverizers. The equipment is to be hauled to the mine from Emigrant Gap.

The work of unwatering the old shaft of the Brunswick mine, Grass Valley, is in progress. It was allowed to fill with water two years ago. The pumping out of this shaft is expected to result in draining the new 450-ft. shaft, in which work is to be resumed as soon as it is free of water.

San Diego County

The Universal M. & D. Co. is developing what formerly was known as the Noble mines, situated 60 miles northeast of San Diego. It is claimed that a large tonnage of ore has been exposed; that there are four veins, the ore found in which assays $5 to $45 per ton in gold that occurs partly free and partly associated with arseno-pyrite. There is a small mill on the property. The mines are in the Julian district.

Shasta County

The executive committee of the Shasta County Farmers' Protective Association, after hearing the report of Frank Gould, who spent two months in analyzing the fumes emitted by the smelter at Coram, decided that the Balaklala Copper Co. was not complying, according to its ideas, with the conditions of the decree of the U. S. circuit court made July 24, 1910, and concluded to place the evidence before the court and ask that action be taken to enforce the decree, which may result in the closing of the plant. The Balaklala company has made heavy expenditures and brought to bear much skill in diluting the gas and precipitating solid matter, but the farmers demand that none of the latter be allowed to escape.

Sierra County

(Special Correspondence.)—Sinking is progressing at the Standard mine, in Sailor ravine, and the manager contemplates getting a small compressor and air-drills. It is probable that a 5-stamp mill will be erected this summer. At the Sierra Buttes 37 men are employed and 20 stamps are operating. The flume has been repaired sufficiently to carry water for power purposes. Plans are being made to improve the mill so as to lessen the cost of treatment. The Rio Antigua Co. of Los Angeles has renewed its bond on the South Fork property at Forest, and it is understood that operations will be resumed. Several rich leads of gravel have been opened, and it is expected to intersect the main channel by extending the adit.

Downieville, May 20.

Siskiyou County

The Grizzly mine, idle for 25 years, is being cleaned out, so that it may be examined by those who are considering a proposal on the part of the owners to sell it.

Tuolumne County

(Special Correspondence.)—The original Black Oak vein, from which more than a million dollars was taken, and which was lost a few years ago, was uncovered on the fifteenth level last week. It is about 5 ft. wide and contains rich ore. The finding of the vein below the fault is of great interest, and it is believed the sale of the property, owned by Scott, Dowe & Co., to the present operators, a company headed by Charles Knox, is assured. R. C. Knox is superintendent. Operations ceased at the Berkeley mine a few days ago and simultaneously a suit was instituted in the Superiar Court of this county by the Berkeley Mining Co. against Ida Klein, William Beddig, Louis H. Beddig, and L. G. Baum for the recovery of $32,000 expended in equipping the property with machinery and making other improvements and for an additional sum of $10,000, which was the initial payment made in November, 1910, on the purchase price of the mine. In the complaint the defendants are accused of 'salting' the mine and of making sundry misrepresentations, on the strength of which the plaintiff company alleges it purchased the mine and erected machinery, including a 10-stamp mill. The men to whom the property was sold are W. J. Wyeth, G. E. Turman, and R. F. Buzard. The Flotilla Gold Mining Co. will commence the development of the Blue Bell group of three claims, four miles south of Tuolumne. A cross-cut will be driven to tap the Blue Bell vein at a vertical depth of 410 ft. The shaft and drifts on this claim reveal a vein 4 to 7 ft. wide. 18 in. of which will mill about $12 per ton in gold. The ore also contains 1% sulphide which assays $450 per ton. The officers of the company are C. H. Burton, president; D. Pennington, vice president, and U. S. Burton, secretary-treasurer. The mill just completed at the Gianelli mine is making its initial run on ore that is high grade. A. C. Mohr and F. J. Gellespie have purchased the Rawhide Extension mine and intend to commence operations.

Tuolumne, May 20.

COLORADO

Lake County (Leadville)

William Harvey and his associates have leased a part of the Resurrection mine, and intend shipping ore through the Yak tunnel. The Louisville mine, also being operated through this tunnel, is yielding 35 tons per day of zinc sulphide. The Maid of Erin, Wolftone, and Henrietta, now referred to as the Nicholson mines, are producing 150 tons per day of zinc ore, which is shipped to the Kansas zinc smelters. It is said the output of these mines is to be in-

creased to 200 tons in June, and to a still greater tonnage by July. The body of zinc ore exposed in the Chrysolite mine is 10 ft. wide, the ore mined averaging 36% zinc. Shipments from the New Monarch mine, Big Evans gulch, continue at 100 tons per day, the ore having a value of $20 to $25 per ton.

La Plata County

The owners of the Neglected mine are reported as having decided to erect a 7-mile aerial tramway from the mine to Hermosa, where a mill and cyanide plant are to be built. Tests were made by John Gross to determine as to the adaptability of cyanide treatment to the ore.

Ouray County

The Mono-Baltic Mining & Smelting Co., of Boston, is erecting a smelting plant at Ironton, the old Saratoga mill building being utilized. This company is developing a number of mining claims, and is said to have plenty of ore.

Park County

The Colorado Gold Mining & Smelting Co., owner of the new pyritic smelter at Alma, recently purchased the Grover and Winnie patented claims and the Atlantic group of 23 claims. The price reported is $30,000.

Summit County

(Special Correspondence.)—The St. John 500-ton mill, which was completed last November, but was operated only

ST. JOHN MILL, MONTEZUMA.

30 days to make a few tests of the dump ore, of which there is a large tonnage, is to be put in operation again this month. The company has signed a contract with the Montezuma Automatic Transportation Co. whereby the latter is to deliver crude ore and concentrate from the St. John mine to the Colorado & Southern railroad at Key-

PENNSYLVANIA MILL, ARGENTINE.

stone. This is an old property that formerly operated at a profit. It is now equipped with electric power. It is understood that the mine is to be retimbered.

The Pennsylvania mill is being enlarged to 250 tons capacity, by the addition of another set of 14 by 27-in. rolls, and two 6-ft. Chilean mills; the method used for concentration during the last year resulted in making a saving of from 75 to 80% of the value. No changes except as to capacity will be made, and the enlarged mill will be in operation by July 1.

Montezuma, May 10.

IDAHO

Boise County

(Special Correspondence.)—The Golden Age Mining Co., E. R. Abernethy, manager, operating near Grimes pass, on the eastern rim of the Boise basin, five miles above Pioneerville, has the mine opened to a depth of 250 ft. by means of a 1200-ft. cross-cut. The vein strikes northeast-southwest, and occurs in granite and porphyry. The two parallel veins, developed near the surface, have been opened on the lower level. A Sullivan single-stage air-compressor has been ordered, and as soon as it is ready for use work will be commenced on a vertical, 2-compartment shaft, to be sunk in the hanging wall, starting at the lower cross-cut. The property has a 15-stamp mill, with plates, classifiers, and tables, in which 40 tons of ore, running $10 to $12 per ton, is being treated daily. About 75% of the total saving is effected by amalgamation. Three classes of concentrate are made, consisting of lead-zinc, which carries the greatest values; a straight iron sulphide, running $50 to $60 per ton; and a second-class concentrate, which is stacked at the mill to await future treatment with cyanide. The concentrate is hauled to Boise, a distance of 49 miles, at a cost of $7.50 per ton. An interesting feature in mining here is the soft character of the ore, only 1000 lb. of powder having been used to mine 6000 tons of ore.

Idaho City, May 20.

(Special Correspondence.)—E. S. Robinson is operating, as lessee, the Boise Basin Hydraulic & Power Co.'s placer property lying east of Placerville. This property consists of 500 acres of placer ground, having an average depth of 65 ft., 40 ft. of which contains gold in paying quantity. The prospect shafts sunk ahead of hydraulic operations show an average of 30c. per cubic yard. Hydraulic operations were commenced about April 1, with a force of 18 men, at an average wage of $3.50 per day. Water is flumed and ditched from Grimes creek, a distance of 35 miles. When a full head is running, about 1000 in. is available, which is sufficient to keep the two No. 3 Hendy giants in operation; the working head is 165 ft. This year the season is expected to last till August 1, and the amount of dirt to be moved is estimated at 115,000 cubic yards.

Placerville, May 20.

Idaho County

The Hercules mine, 15 miles east of Elk City, owned by Johnson and Comley, is fairly well developed by surface work, and a 405-ft. cross-cut, the latter giving a depth of 230 ft. on the vein. Drifts, amounting to 200 ft., have been driven from the place where the vein is tapped by the cross-cut; this work shows the vein to be 6 ft. wide, and to contain some rich ore. The same vein was opened by another cross-cut, 90 ft. below the apex, and a raise was driven in ore to the surface. The Anaconda mine, in Ten-Mile district, has been leased for a year to W. Newton, C. Whipple, B. Jones, G. McDonald, and F. and C. Smith. The property has a 900-ft. cross-cut, by which the vein was not opened as expected. The lessees will work at a higher point where the ore is exposed. They expect to operate the 5-stamp mill, and will form a company called the Idaho Leasing & Exploration Company.

MONTANA

Silverbow County

(Special Correspondence.)—Miners are at work in the Colorado mine of the Davis-Daly company for the purpose of doing development work on the 1700-ft. level, in accordance with the recommendations of W. H. Wiley, who examined the mine some time ago, and they declare that the rich body of ore, uncovered on that level some time ago, still continues and will run about 10% copper.

The High Ore mine, which had to be closed down last fall in consequence of a fire in the lower levels, is being operated again, about 500 tons of ore per day being hoisted. All sign of the fire, which at one time was threatening, has disappeared, and the air is as clear as it ever was.

Butte, May 20.

NEVADA

Elko County

The Tuscarora-Nevada Mines Co., controlling a number of mines in Tuscarora camp, has placed W. A. Farish, Jr., in charge, and is having the orebodies sampled. The properties are well developed, the deepest workings being through a 600-ft. shaft. The formation of the district is made up of rhyolite and andesite, the ores occurring mostly on the contact of these two. The stock of the company is said to be in control of New York men.

Humboldt County

The Salt Lake-Winnemucca company, in which J. H. and J. P. Turner and others are concerned, has leased a block of ground on the Adamson-Turner group, near Winnemucca; the block leased is 900 ft. north of the Adamson-Turner shaft. The owners of the group are having a 200-ft. cross-cut driven to open the vein at greater depth. The heading of this work is now close to the vein.

Lander County

(Special Correspondence.)—The Austin Manhattan company recently shipped 600 sacks of high-grade ore from the Jack Pot, 200 sacks from the Panamint, and 250 sacks of concentrate from the mill.

Austin, May 10.

Lyon County

(Special Correspondence.)—The stockholders of the Nevada-Douglas Copper Co., at a recent meeting held at Salt Lake, elected officers as follows: President, A. J. Orem; vice-president, James G. Berryhill; second vice-president, L. H. Curtis; treasurer, W. V. Rice; secretary, Frank M. Orem; general manager, W. C. Orem. The mine of the company is in the Yerington district, at the terminus of the railroad which is built from Wabuska into this district. This company is under contract to ship a specified tonnage of ore to the smelter that the Mason Valley Mines Co. is building at Thompson, near Wabuska.

Mason, May 20.

Storey County (Virginia City)

The Mexican G. & S. M. Co. has been having tests made on ore from its mine to determine the character of treatment to be adopted for the proposed mill. The ore contains gold and silver, associated with sulphide material, in a gangue of quartz and silicified porphyry. There are low percentages of lead and zinc, but these do not figure on the commercial side. It is probable that the mill treatment to be adopted will not differ much from that in use at the Tonopah mills. For the week ended May 20, there was mined 51 cars of ore, averaging $75.84 per ton, on the south drift from the east cross-cut No. 2, and 51 cars of ore, running $11.70 per ton, on the north drift, same cross-cut, at the 2300-ft. level; on the 2400-ft. level, 51 cars of ore, averaging $14.70 per ton, were taken from the west cross-cut off the north drift; there were 66 cars of ore, assaying $89.66 per ton, taken from the twelfth floor of the raise between the 2500 and 2400-ft. levels; also, 9 cars of ore, assaying $33.73 per ton, at the foot of this raise. Shipments to the smelter for the week amounted to 8 railroad-car loads.

The Union shaft, used jointly for the Mexican, Union, and Sierra Nevada mines, has a depth of 2000 ft., from the bottom of which is a drift 1450 ft. east. A winze is being sunk at the farther end of this drift by the Sierra Nevada and Union companies, the winze having reached a depth of 300 ft. The new orebody in the Mexican mine, now of so much interest, was found by sinking a winze from its 2200-ft. level, and cross-cutting at 2500 ft. The latter winze is on Mexican ground 140 ft. from its boundary with the Union; another cross-cut was made from the winze to the orebody at 2400 ft. Then a raise was driven on the vein from the 2500 to the 2400, the upper part of the raise being in ore that sampled over $100 per ton. The ore-shoot at and above the 2500-ft. is pretty well demonstrated, but what lies below this is yet to be determined by lowering the water-level by means of the pumping plant at the 2100-ft. station of the C. & C. shaft, which discharges water into the Sutro tunnel at the 1700-ft. station. The Mexican company is shipping its high-grade ore to the smelters, reserving its low-grade for the mill that is to be built this season.

The Julia Con. M. Co., which has an area of ground at Virginia City, lying in the vicinity of the Exchequer, Bullion, and Potosi, operated profitably from 1875 to about 1880, but since that date the property has been idle, and within that period the Julia shaft and workings have badly caved. Records of those early operations indicate that extensive bodies of ore, assaying $10 to $20 per ton in gold and silver, were opened on the 1600 and 1800-ft. levels. This ore was not mined, as it was too low grade to handle profitably at that time. In order to re-open the old workings and get at the orebodies, a drift is being driven from the 2000-ft. station of the Ward shaft, and the Julia ground will be tapped at about 300 ft. beyond the present heading.

White Pine County

(Special Correspondence.)—A new steam-engine of 50-hp. capacity is being put in position at the Zack shaft of the Ely Consolidated company and will be in use in a few days. The management has demonstrated the existence of extensive bodies of sulphide ore running 6% copper on the 500-ft. level, which has encouraged it to sink deeper, and for this purpose the new engine is to be utilized. About 600 ft. of work has been done on the 500-ft. level, the greater portion of which is in commercial ore, much of it averaging 6% copper.

The Steptoe Valley Mining & Smelting Co. is now using oil for fuel in two of its reverberatory furnaces at McGill, which it is estimated will effect a saving of at least $25,000 per year in cost of fuel. The other three reverberatories will be equipped for oil burning during the year, as this kind of fuel is giving good satisfaction. The power plant probably will not be equipped for using fuel oil during this year, as there is a large tonnage of coal on hand, which will be used up before making the change. When the entire plant is equipped for oil burning, it is expected that a saving of $100,000 per year will be made by changing from coal to oil. Basic converters are being provided at the converter plant, one of which will soon be in use, and two others later in the summer. The concentrating-plant is treating an average of 10,000 tons of ore daily.

A definite statement has come from what seems to be reliable source that the Eureka-Palisade railroad will be reconstructed during the present year. This will result in reviving the mining industry of Eureka, Windfall, and Hamilton, which has been inactive since this railroad was washed out 18 months ago.

The management of Boston-Ely has found sulphide ore of importance in the west cross-cut on the 1245-ft. level, which is expected to lead to deposits of commercial ore beneath the water-level. The Boston-Ely has made a long, hard fight, and present indications are that it will yet win out by bringing in another producer for the Ely district.

The Giroux Consolidated, which has the best-equipped shaft in the State, will soon be in the producing class. Its cross-cut on the 1200-ft. level is now nearing the orebodies developed in the old Alpha workings, while the cross-cut on the 1400-ft. level is also being driven in the same direction, but the heading of which will not reach the ore zone for two or three months. No announcement has been made recently by the management of the company in regard to the erection of a plant for treating its ores in the district, but it is probable that shipments of high-grade ore will soon be commenced.

Ely, May 22.

UTAH

Beaver County

The Utah M. M. & T. Co., developing the Hub and Lady Bryan claims in Star district, 10 miles from Milford, has completed its main working shaft to a depth of 400 ft., and

cross-cuts have been driven to the vein from the 300 and 400-ft. stations. Drifts have been extended on the vein at the 300-ft. level, and a considerable tonnage of ore has been stoped and shipped. Some ore is also mined from the bedded veins which come into the main lode. The bins are full of ore and there is a big tonnage exposed in the mine. C. T. Birchard of Boston is the company's manager.

JUAB COUNTY

The Carisa Gold & Copper M. Co., having 57 acres of patented ground in Tintic district, near that of the Centennial Eureka, has leased a part of the property to Fred T. Williams, of Park City, who is to begin development and mining. Operations are to be continued also on company account. The ore shipments from Tintic district for the week ended May 20 were 146 cars. The five largest shippers were the Iron Blossom, 33 cars; Centennial Eureka, 29; Dragon, 27; Colorado, 10; Grand Central, 7 cars.

TOOELE COUNTY

(Special Correspondence.) — The Consolidated Mercur company sent $50,000 in gold to the Government assay office at Salt Lake as a result of April operations. The mill treated about 22,000 tons of ore, indicating how low a grade of ore is being handled at this mine. The Utah mine, at Fish Springs, produced nearly $7000 worth of ore during the first two weeks in May. This mine has been producing silver-lead ore for twenty years of a grade high enough to make it profitable to haul it by wagons 75 miles to the nearest railroad station.

Mercur, May 22.

CANADA

BRITISH COLUMBIA

(Special Correspondence.)—James Breen, of Spokane, who owns 75% of the stock of the McKinley Mining Co., having a partly developed mine on the north fork of Kettle river, 34 miles up-stream from Grand Forks, has bonded the property to the British Columbia Copper Co., at $100,000, one condition being the continuous development during the next 12 months. The B. C. company is to develop more extensively by means of a long adit.

Grand Forks, May 20.

(Special Correspondence.) — The Rambler-Cariboo M. Co., having properties near McGuigan, with W. E. Zwicky as manager, has opened on the 1250-ft. level a shoot of ore, containing 6 to 8 in. of clean galena. Other openings on the orebody are on the 700, 800, 900, and 1050-ft. levels. It is said the shoot is 35 ft. long on the 700-ft. level, 82 ft. at 800, and 200 ft. in length on the 900. The shoot is only partly developed at the 1050, but where the ore is exposed it has a width of 4 ft., and consists of galena. Ore from the 900-ft. level sampled 65% lead, and 117 oz. silver per ton; the clean ore taken from the 1050-ft. level ran 75% lead and 250 oz. silver.

Sandon, May 19.

(Special Correspondence.)—The Soho Con. Mines, Ltd., which formerly shipped ore of the value of $45,000 from its silver-lead mine near Sandon, will resume work again June 1. The property adjoins the Rambler-Cariboo, in McGuigan basin. J. C. Ryan, manager, states that the ore will be hauled to Kaslo by rail, then shipped to Trail by water.

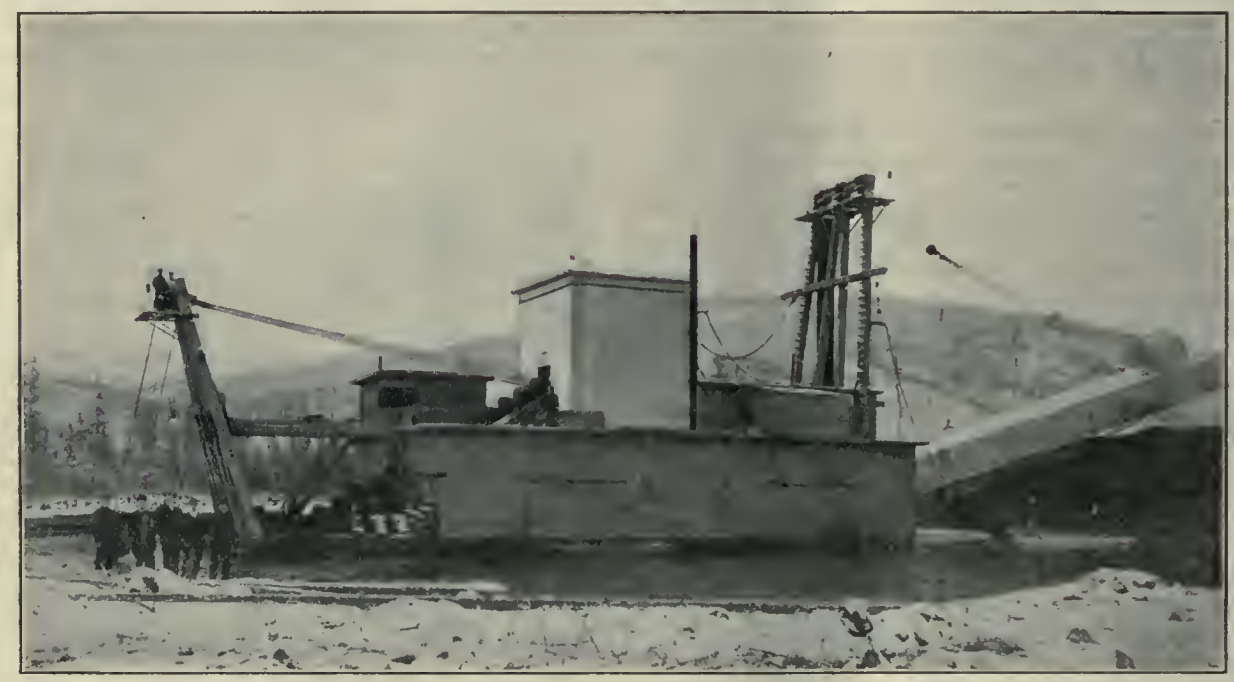
Sandon, May 15.

(Special Correspondence.)—The Granby Con. Mining, Smelting & Power Co., which has purchased the mines of the Hidden Creek Copper Co., near Observatory inlet, on Portland canal, has decided to erect a smelter in the vicinity of the property, but the plant will be on deep water, so that the slag can be disposed of economically. The new cross-cut being driven is to tap the copper lode at a depth of 800 ft.; the portal of the cross-cut is a mile from the site selected for the smelter.

Prince Rupert, May 16.

(Special Correspondence.)—The Kootenai Mines, Ltd., has become owner of the Granite-Poorman mine, situated in Nelson country, by the payment of $10,000 on the old Duncan-United Mines bond.

Nelson, May 18.



CANADIAN-KLONDIKE DREDGE ON BEAR CREEK, NEAR DAWSON.

YUKON

The ice in the Yukon river started to go out May 15, and the steamer *Canadian* sailed from White Horse, May 19, with passengers and freight for Dawson. A heavy output of gold dust is anticipated this season from the Dawson district, as the result of dredging and hydraulic mining. The main operations are on the upper tributaries of the Klondike river, comprising Bonanza, Hunker, and Bear creeks. The most extensive dredging operations there are those of the Yukon Gold Co., though the Canadian-Klondike M. Co., Northern Light, Treadgold, and others are operating several dredges. The Canadian-Klondike company, having two dredges on Bear creek, began work with one dredge before May 1, Joseph W. Boyle being manager.

Decisions Relating to Mining

Specially reported for the MINING AND SCIENTIFIC PRESS.

INJURY TO MINER—ASSUMPTION OF RISK

An experienced blaster in a granite quarry is presumed to have knowledge of such open and obvious dangers incident to doing blasting as such a skilled person of ordinary intelligence and knowledge possesses, whether they arise from the business, the particular manner in which it is conducted, or the use of defective or unsafe appliances. Such an experienced blaster is presumed to know the nature and condition of the blast-holes as to roughness and unevenness of the side or of sharp projections of the rocks in the walls, and knowing these facts he is charged with the knowledge that the use of a steel rod in a blast-hole might produce a spark by contact and friction with the rock, and thereby produce premature explosion. The danger from premature explosions arising from the use of a steel rod in a blast-hole is the result of known and obvious conditions of the operations of natural laws, and it cannot be said to be a secret and an unknown danger which an intelligent and experienced blaster does not comprehend. It is not improbable that an expert blaster has more knowledge concerning the art and a better comprehension of such dangers than the employer himself, who is held to have full knowledge of such in the conduct of his business; and the dangers incident to the mode of blasting are the risks and hazards which attend such work, and are the obvious and known dangers incident to the manner of conducting the blasting operations and which are assumed by the servant in his employment and undertaking the work. It is immaterial that an experienced blaster, injured by a premature explosion caused by a spark in the use of a steel rod in the blast-hole, had no knowledge of the process and dangers of blasting except what he had acquired while at work in the quarry of his employer, as such want of knowledge from other sources does not relieve him of the assumption of the risk of danger arising from the use of a steel rod in loading blasting-holes with powder, where he did in fact comprehend and understand the danger.

Brotzki *v.* Wisconsin Granite Co., (Wisconsin) 125 Northwestern, 916. April 1910.

BREACH OF CONTRACT TO LEASE OF MINE—PROFITS

In an action for breach of a contract to lease the right to operate a mining claim on a royalty, proof that the owner stated to the complainant that he would make out a lease of the claim and that the terms of the royalty would be 40%, and that the lease was to commence at a date named and extend to another named date, was held sufficient as to the terms of the lease and as a basis for the recovery of damages. It was held also that the lessee would be entitled to such profits as would have been derived from the premises for the full period of the term for which the lease was to have been made, and that proof of such profits might be made by showing the profits made under a like lease of the same property to other parties during the same period, if it is shown that the lessee would have worked the premises practically in the same manner had the lease been executed to him according to the agreement.

Hjelsberg *v.* Chilberg, 177 Federal, 109. Feb. 1910.

MINERAL RIGHTS IN RAILROAD RIGHT OF WAY

A deed conveying to a railroad company a right of way containing the clause "coal rights reserved," was held to reserve the title to the coal under the right of way and that it separated the title to the coal from the title to the surface, together with the mining rights connected with it, and that the grantor could mine and remove the coal and could use the space where the coal was found in any way he pleased and as though no conveyance of the surface had been made.

Personal

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

HOWARD D. SMITH is in London.

GELASIO CAETANI is in New York.

C. A. FISHER was in Texas last week.

T. R. MARSHALL has moved to Mexico City.

H. A. J. WILKINS has returned to New York.

F. G. COTTRELL has gone to Placerville, California.

EDMUND JUESSEN has returned from Blair, Nevada.

FREDERICK G. CLAPP is examining oil properties in Mexico.

C. F. TOLMAN, JR., will spend next year in European travel and study.

BERNARD MACDONALD was at La Jolla, California, and has gone to New York.

GEORGE S. RICE, of the U. S. Bureau of Mines, will sail for Europe June 17.

E. COPPEE THURSTON arrived in New York on May 12 from South America.

F. W. BRADLEY and ERROL MACBOYLE will sail from Seattle for Juneau, May 31.

CHARLES JANIN and H. FOSTER BAIN left on Thursday for Globe, Arizona, and Denver, Colorado.

W. A. FARISH, JR., is superintendent for Tuscarora-Nevada Mines Co., operating at Tuscarora, Nevada.

FRANK L. COLE and RUSSELL Y. HANLON have formed a partnership at Manila as consulting mining engineers.

W. H. NORTH, formerly of Wallace, Idaho, is now with the Standard Silver-Lead M. Co., Silver, British Columbia.

F. H. RICKER, of the Merrill Metallurgical Co., is at Colorado City preparing drawings for changes at the Union mill.

MORTON WEBBER, of New York, has been in eastern Canada on examination work on behalf of the C. L. Constant Company.

E. S. BASTIN and J. M. HILL will return to Colorado June 1, to resume the geological survey of the Central City quadrangle.

GEORGE H. CUSHING has been made secretary of the local executive committee of the American Mining Congress, for the Chicago meeting.

R. H. CHAPMAN will continue his work for the Canadian Geological Survey another season and will make headquarters at Victoria, B. C.

BURROUGHS EDSALL has been engaged in re-opening the old silver mines on Blind Spring Hill at Benton, California, since January 1, 1911.

D. C. JACKLING, general manager, and FRANK JANNEY, mill superintendent, for the Utah Copper Co., are inspecting the Ray and Chino mills.

CHARLES H. FULTON, president of the South Dakota State School of Mines, at Rapid City, has resigned to take the chair of metallurgy at the Case School of Applied Science, Cleveland.

Major SHERWOOD A. CHENEY, of the Corps of Engineers, has been appointed a member of the California Débris Commission in the place of Captain THOMAS H. JACKSON, Corps of Engineers, relieved.

FERDINAND H. GRASER has resigned as secretary of the Nevada Wonder Mining Co. to become assistant secretary of the Colombia Consolidated Goldfields, Inc., with offices in the Bailey building, Philadelphia.

WILLIAM B. FISHER, who for the past four years has been manager for the Salt Lake Copper Co., with offices at Salt Lake City, has resigned to enter the employ of the American Smelting & Refining Co., his headquarters being in the New York office.

Company Reports

LIBERTY BELL GOLD MINING COMPANY

The annual report of this company for the year ended September 30, 1910, shows that during the year its mine at Telluride, Colorado, produced 887,606 tons of ore, which, when milled, produced stamp bullion to the value of $511,410, cyanide products worth $318,045, and concentrate to the value of $125,498, other incidental receipts making a total of $988,604. The total operating expense was $706,458, leaving a profit balance of $282,147. The following comparative table of receipts and costs per ton is of interest:

RECEIPTS.

	Rate per Ton.		
	1910.	1909.	1899-1910.
Stamp bullion	$ 3.82	$ 3.06	$ 4.18
Cyanide products	2.38	2.06	1.95
Concentrate	0.94	0.43	0.83
Slag	0.03	0.02	0.02
Ore proceeds (133,899 tons)	$ 7.17	$ 5.57	$ 6.98
Boarding-house, tram, rents, mine-commissary profit, interest and profits from investments	0.21	0.33	0.15
Average receipts per ton milled	$ 7.38	$ 5.90	$ 7.13

EXPENSES.

	Rate per Ton.		
	1910.	1909.	1899-1910.
General expenses (133,899 tons)	$ 0.41	$ 0.39	$ 0.78
Mining (134,321 tons)—			
Operating	2.32	2.36	2.75
Development work (5374 ft.)	0.29	0.49	.....
Tramming (134,373 tons).	0.19	0.29	0.36
Milling (133,899 tons)	1.73	1.67	1.72
Treatment and shipping costs	0.32	0.19	0.31
Stamp bullion (59,873 oz.)	0.04	0.03 per oz. bullion	
Concentrate (2503 tons)	14.97	12.98 per oz. concentrate	
Cyanide bullion (174,764 oz.)	0.02	0.02 per oz. bullion	
Average cost per ton milled	$ 5.27	$ 5.40	$ 6.07
Profit per ton milled	$ 2.11	$ 0.51	$ 1.08

The decrease of 24c. per ton in mining cost and 10c. per ton for tramming is noteworthy. During the year extensive alterations have been made in the mill, and it is hoped thus to decrease the cost of milling. The following table shows the work of the mill for 1910:

ORE MILLED, 1910.

(133,899 tons.)

Gross values per dry ton milled, and percentages.

	Gold.		Silver.		Value.	
Recovered—	Oz.	%	Oz.	%	$	%
In stamp bullion	0.178	57	0.254	7	3.82	46
Concentrate	0.026	8	0.651	19	0.94	11
Cyanide products	0.086	28	1.162	34	2.41	29
Total recovery	0.290	93	2.067	60	7.17	86
Lost—						
In tailing	0.021	7	1.381	40	1.17	14
Total content	0.311	100	3.448	100	8.34	100

The percentage of recovery has continually increased and is now 8% better than the average for the last 12 years. Depreciation has been provided for, $30,836 being set aside for this purpose. The net gain for the year was $282,147; dividends amounting to $143,606 were paid, corresponding to 22% on the capital; the balance added to that of the preceding year amounting to $629,525. The schedule of stocks and bonds shows that these amount to $190,215. The capital is given as $700,000; 9445 shares have not been issued.

TABLE OF CONTENTS

EDITORIAL

THE stratigraphy of the Globe-Ray region has taken on added importance with the development of the great masses of copper-bearing porphyry. On another page Mr. F. L. Ransome points out some differences in the sections at Ray and Globe, giving the results of the most recent study of the area.

IN the development of a prospect the problems which arise are numerous and varied. The keeping of adequate records with a minimum of effort is not the least of these, and many of our readers will find much that is helpful and suggestive in the discussion of 'Simple Mine Bookkeeping', by Mr. K. C. Parrish.

AUSTRALIAN contributions to the advancement of the art of cyanidation have been noteworthy. We present this week a discussion of the methods of slime agitation practised in Kalgoorlie, by Mr. M. W. von Bernewitz. The metallurgist of the Associated is in a position to speak as one having authority, and his contribution will be read with interest.

THE one hundredth meeting of the American Institute of Mining Engineers will be held June 6 to 10 at Wilkesbarre, where, in the anthracite region of Pennsylvania, the Institute was organized forty years ago. Excursions to near-by collieries and coal breakers, the Bethlehem steel works, and the Lehigh University, will be among the features of the meeting. A list of more than thirty papers is announced and it is safe to say that none will prove of greater general interest than the 'Reminiscences of the Beginning of the Institute' by the veteran Secretary, Dr. R. W. Raymond.

AN interesting international incident is the recent visit to Berlin of Charles M. Schwab to confer with leaders of the Russian and Scandinavian steel industries. The export to the United States of Scandinavian iron ore and the expansion of the Swedish and Russian navies were the topics under discussion. At home it is announced that Mr. W. E. Corey and Mr. H. C. Frick have acquired 30,000 acres of coal land near Blairsville, Pennsylvania, and will proceed to erect a large steel plant at that place. The steel trade is now improving, and orders have been issued to blow-in several furnaces that have been shut down.

THE retirement of Mr. Lewis T. Wright from the active management of The Mountain Copper Company, Ltd., takes from us a brilliant scientist, who has added lustre to the mining fraternity. It is but seldom that an engineer combines with business ability such a mastery of pure science as does Mr. Wright. This extraordinary knowledge of pure science is the more remarkable in his case, since Mr. Wright represents a class of engineer that has few representatives today. He is the product of the old system of apprenticeship, as contrasted with the technical graduate. At the age of nineteen he was junior assistant engineer of

the London Gas Light & Coke Company, and at twenty-seven, chief engineer of the Corporation Gas Department of Nottingham. Later he went to Buenos Ayres as chief engineer of the gas company there, finally entering the employ of the Rio Tinto Company, Ltd., to solve the problems arising at its American venture at Kennett. His brilliant work there in the development of pyrite smelting and the advancement of the metallurgy of copper is too well known to our readers to need any recital. Mr. Wright has now retired to London, though it is possible that he may return to the United States, for a period at least. He is succeeded in the management of The Mountain Copper Company, Ltd., by Mr. William F. Kett, who has for many years ably seconded Mr. Wright's labors as his chief assistant.

THE merger of copper interests, so long mooted, seems now a possibility. The basis upon which to come together is naturally a matter of discussion. The plan has been suggested of forming four groups, Butte, a southwestern group, a Utah group, and a Mexican and South American group. As a preparatory step it is proposed to gather the 'porphyry coppers' into a single corporation with D. C. Jackling at its head. The copper market has begun to advance, but it is not at all unlikely that the merger discussion is intended more largely for market effect than with a view to action. It is difficult to see how the controlling interests in copper can even now get together without finding themselves outside the pale of the law. It is realized by both producer and consumer that a great waste of natural resources is involved in the production of copper under present circumstances. A large quantity of metal is being placed on the market at no profit, and an almost equally large amount is being produced at an actual loss. Taking depreciation charges and the lessening of ore reserves into consideration, it is doubtful whether profits as now computed should not be materially reduced in estimates. It is certain, at least, that nothing will be done toward forming a merger until after the United States Supreme Court hands down its decision in the Tobacco Trust case.

The Supreme Court Decision

Umslopagus, wise, black, and ancient, meditates in one of Rider Haggard's Allan Quartermain stories on the limitations of mankind, saying, "Human nature is like an iron ring; you can polish it and polish it, you can even bend it in a little on one side, whereby you will cause it to bulge out on the other, but it is an iron ring just the same." The world has always gone its way striving for the next turn in the hard and dusty road to lead it into rich pastures along shaded paths. Always the promised land will be seen from the next hilltop. For many months discussion in the business world has centred about the Trust cases before the Supreme Court of the United States. At length patience has been rewarded and the decision in the Standard Oil case has been handed down. Everyone in the 'Who's Who' of the business world has been careful to be interviewed therein. The fact that a scathing rebuke was administered to the defendant, the Standard Oil Company, is the matter last and least discussed. The exceedingly human thing about all of the discussion is that this new turn in the road reveals very much the same old landscape, the same wearying problems of the same old world.

So far as Wall Street is concerned, it has adopted the attitude of the late Tom Reed, Speaker of the House of Representatives, who, having answered an annoying member on the floor, turned to the House with: "Having embalmed that fly in the amber of our remarks, we will take up the regular order of business." All through the Street there is a bold putting forward of the best foot, with an outspoken invitation to the public to join in the activity supposed to be ready to begin. There are those who yet insist that the important economic question involved is still unsettled, and the noise of discussion drowns the hum of the stock market. Sales of securities have been negligible for a long time. Any event that would serve as an excuse for urgent invitation would answer for stock market purposes. Time and proper perspective only can make possible a just estimate of the judgment of the Court. The comment of the day is meaningless, and already the hope is expressed that the decision in the Tobacco case will, when rendered, shed further light. Already the next turn in the road, the new hilltop, has been sighted. Mr. Justice Harlan's vigorous dissenting opinion establishes a strong foothold for those who would combat the position taken in the majority opinion. Wall Street professes to see a great victory and an era of expansion, development, and prosperity is at hand.

Many Inventions

In a notable address delivered at the dedication of the new mining building of the University of California in 1907, Mr. T. A. Rickard pointed out the great need of some arrangement in university work whereby the professors of technical branches might find ample opportunity for keeping more closely in touch with the development of actual practice than they, as now situated, are able to do, and suggested that the most feasible way to secure this would be for someone of great wealth to endow the departments so liberally that a double staff might be employed, half of which should be engaged in carrying on the teaching work, while the rest were in the field observing practice. But since no wealthy patron of learning has so far shown a disposition to provide the necessary endowment, Mr. J. F. Kemp has found opportunity in a busy life to devote time to the solution of this problem, and we are enabled to present upon the following page, the details of his invention which makes it possible for a professor to be absent from his classroom for long periods without serious loss to the academic work. Education has so universal an appeal that our readers will find much of interest in Mr. Kemp's solution of this educational problem.

The principal question of every student is how to secure a real education. An education is an individual possession, therefore a solution of the problem must be an individual solution. Generalization upon a subject of so varied an aspect is impossible, except the generalization that an education can never consist of the mere obtaining of information upon certain selected topics. What more his nature needs, each student must find for himself, aided by the men under whom it is his privilege to sit while yet an undergraduate. The 'freshwater college', as Holmes half-contemptuously designated it, has been a powerful factor in the development of education in America, and one of its great elements of strength has been the opportunity afforded for the students to come into closer personal contact with their instructors. A great university affords but little opportunity for this, and there are many Columbia students who would rate above the hours spent upon petrography and paleontology those when,

"Now every year, it doth appear,
The men of rocks sit down
To eat a bite, and with good right
The long year's efforts crown.

So take a cup and fill it up
To friends now far away,
And quaff again the cup amain
To those who with us stay."

The Photophonic Lector

By J. F. Kemp

*The photophonic lector is nothing more nor less than an endeavor to have professors as well as other people profit by the marvelous latter-day inventions such as the photographic camera, the telephone, and the phonograph. Almost every calling except our own has been benefited by them. The camera, to be sure, has been useful, but the telephone has proved a great drawback. It places us in such easy communication with the Dean and the President that nowadays it is impossible to get any time to ourselves. So far as professors are concerned, the phonograph might just as well never have been invented. I therefore determined to combine the principles of all three in the photophonic lector.

The photophonic lector is a device which will take the place of a professor in a lecture-room. It is designed so that a book or a typewritten manuscript may be inserted in a proper carrier, so arranged that by mechanical fingers moved by adjustable clockwork the pages are turned from time to time and at the exact instant. This is easy of attainment and means no more than doing with a machine what is done by the man of limited intelligence who turns the pages of a music score for a performer at the piano. In the photophonic lector the book or manuscript is carefully boxed so that none of the fierce light thrown upon its pages by an electric arc lantern escapes into the room. That is to say, we have the pages illuminated in the most brilliant manner, so that the contrasts of black and white stand out very sharply. I should mention that typewritten matter must be prepared with a good, fresh, black ribbon. Blue or purple ink will not answer, nor can we use carbon copies, which are naturally somewhat blurry and indistinct. Not every typewriting machine is well adapted to making the copy. It requires one with a sharp, clear-cut, staccato mechanism, and the operator must have the same characteristics. An easy-going operator who slurs things over, or who makes irregular spaces between the words, or who, above all things, has to rub out mistakes, will not answer. Nevertheless, all these precautions can be easily observed with proper care in selection.

Now when the book or manuscript is set up in the *camera illuminata* of the machine and when the mechanical fingers for turning the page at the proper instant have been adjusted by a few screws, and the time interval has been exactly set for the number of lines, then the fierce white light of the electric arc is focused upon the page, so that it shines with a radiance like the grand display of the orb of day. This brings us to the second unit in the device.

Close beside the arc-light lantern is set a second box with an arrangement of lenses in a tube, and provided with a little window not unlike the slit of a spectroscope or, again, much the same as we find in the panoramic cameras that sweep the entire arc of the horizon. Let us call it the transmission telescope. The slit in the shutter before the objective glass is just the right size to take in one letter. The telescope is moved by clockwork so that when it is set at the beginning of the first line of the exposed page it focuses upon the first letter, and then the half of the shutter at the right-hand side of the slit is swept by the clockwork swiftly from left to right, picking up letter after letter, so as practically to spell out the word and transmit its image backward. By a simple device which depends on the effect of light upon a selenium cell, the right-hand side of the shutter opens until it encounters the blank white space between two words. So long as a dark letter is transmitted the slit widens, but the instant a white space is met the slit is closed. Thus for an incredibly short time the entire word is transmitted to the sensitive selenium cell of which I will speak in a moment, and then the shutter closes. By careful adjustment this has been made to correspond exactly with the time period occupied in the pronunciation of a word by a speaker who talks at a moderate speed and with musically modulated tones. A very short space will thus automatically be given to words of one syllable, while to certain terms in petrography or in the biologic branches a quite appreciable interval is assigned. The transmission telescope plays along the line until it reaches the end. The clockwork already adjusted snaps it off, drops it the proper distance, and returns it to the beginning of the next line where it automatically begins. It required much experimenting to perfect this, but, after all, speech is slower than sight, and the difficulties are not so great as with the moving pictures which deceive the eye. In fact, you will at once see that the problem is much the same, and if before you had ever seen a moving-picture show I were to have proposed these two things, you would have said that the moving picture was the more difficult.

Thus the transmission telescope plays along from line to line, the words are flashed back to the selenium cell, the page is covered and instantly turned over by the mechanical fingers, and a new one is begun. The movement is gently and musically modulated; the sentences are carefully prepared beforehand, and polished with great literary care and skill. The process has, really, many advantages over the ordinary lecture.

All that now remains is to have the words as they are flashed upon the selenium cell, which I will hereafter call the speaking retina, or *retina parlans,* so affect an electric current that they will pass to a telephone and be uttered to an audience through the medium of a megaphone. That is why I selected selenium. This element, as you know, has its powers of transmitting an electric current affected by the impact of rays of light. Thus, years ago, Graham Bell, in Washington, set up a telephone on the roof of one building, so arranged that the vibrations of the disc affected a beam of light which was flashed by the instrument to a selenium cell in the circuit of another telephone on a fairly remote roof. The interruptions of the beam of light so affected the selenium cell that it caused the receiving telephone to transmit the speech of the first one to the auditor. Precisely the same thing is done by the *retina parlans,* which is in the telephonic circuit. As the letters build up the syllables, the syllables blend together to form the word, which is emitted by the megaphone and passes on to the audience. At the same time when only the white light of the spaces between the words reaches the selenium cell, the disturbance is so great that the vibrations are too quick for speech. They belong among those ultra-violet wave lengths in the realms of silence outside the field of speech. They do operate, however, to close the shutter.

Much experimentation was of course required in the early adjustment of the instrument, but on the whole I found it less difficult than I had anticipated, and as I discovered that I could slip in, for instance, Geikies' 'Founders of Geology', and recalling the charming and well-modulated tones of the gifted author, could by the adjustment of a few screws, apparently hear him before me, I felt enchanted by the results.

But having gone so far, I was led into further experimentation. I reasoned this way. If the photophonic lector succeeds with English, why not with French and German. On trial, it gave me back these languages perfectly, and I was so carried away that I read half of De Launay's great treatise on 'La Geologie et Les Richesses Minerales de l'Asie' at a sitting. Of the natural results of this discovery I will speak in closing. But at the time I reasoned further and then experimented with success as follows:

If we pass a ray of white light through a prism—or, better yet, through one of Rowland's famous gratings—it is broken up into the prismatic tints, any one or two of which we can preserve and transmit by cutting out or absorbing the others.

Now in the case of the photophonic lector the speech is entirely due to the transmission of certain forms of light rays, which spell out certain words. But if I could interpose in the track of those beams, say of German words,

*Address delivered before the Geological Journal Club, Columbia University, May 3.

a grating of the proper construction to turn them into the English equivalents, why, a German lecture would be automatically translated into English and would issue from the megaphone as such. It was so simple that I wondered no one had thought of it before. All I needed to do was to take a few lines of German and start them through. Then I slipped in gratings ruled in various patterns until one gave a fairly good approximation to English speech. Then by slight variations of the shape of the spaces in the grating I finally found the secret. I put in Credner's 'Elemente der Geologie', and presto! it came out in beautiful English. Similar experiments produced a French grating, and I could easily prepare one in almost any language. What I most wanted, however, was Chinese, since, the proper grating once secured, the priceless literature of this ancient kingdom would be mine. So I printed with good black India ink the characters:

壽福

and then experimented with gratings until from the megaphone came forth, "Good luck, health and happiness," and success was mine. Now, with the proper alteration in the transmission teleseope so as to begin in the upper right-hand corner and move downward, we can automatically translate any Chinese work.

But, someone says, all this is very interesting as a scientific experiment, but what will be the applications? Well, without elaborating at too great length, the following occur to me:

First: Sabbatical leaves of absence are made easy. A professor writes out his lectures on a typewriter. He leaves them arranged in serial order, and one for each day, with an assistant. The assistant prepares the instrument and throws in an electric attachment which is connected with the bell in the university circuit. The striking of the bell starts the photophonic lector and immeditely there issues from the megaphone in musically modulated tones: "Gentlemen, we saw at the last lecture that the toes of trilobites are only found upon coral reefs in the calcirudites", etc. The assistant, having meantime marked the roll, leaves the room precisely as if the lecture were an examination conducted on the honor system. For the class the hour passes delightfully. The carefully polished sentences roll forth. There are no trembling "er—er—er"s. The style is immeasurably better than the extemporaneous lectures to which we are accustomed, for of course no professor would ever make a record of what he has the assurance to utter off-hand.

Promptly when the fifty minutes are up, the bell rings and by the same act the electric connection shuts off the photophonic lector. A half-minute is required for the class to recover from the spell which has enchained them, and, forgetful even of cigarettes, they quietly disperse. How different from the present customary beginning, with a professor interrupted and upset by late-comers; irritated that a colleague has kept the class overtime; annoyed by the low hum of conversation; his subconscious self aware of the presence of books or papers not connected with the subject; his faltering utterance; his mixed sentences: why, the contrast is something indescribable.

Second: Let us apply it to exchange professors. At present the Kaiser Wilhelm professor must speak English. The Theodore Roosevelt professor, German. By these conditions the choice is much restricted. But were the appointee provided with a photophonic lector and the proper grating, he could write out his lectures in his native tongue and hear them issue in choice English or German from the megaphone. He might sit beside the instrument and smile or make a few gestures at appropriate times, or he might stay away altogether. He might even remain at home and only send his manuscripts across the ocean—thus avoiding possible conflicts with other exchange professors and exciting frightful jealousies—and in this way immensely relieving the anxieties of the university authorities who would otherwise have to bear with him: there is much to be said for the photophonic lector.

On the other hand, I must admit there are grave dangers lurking in the instrument. Professors having once written out their lectures, might be satisfied, and to an even greater extent than now be led to use the same old matter over and over. They might be tempted to stay away from the classroom; they might be constantly off on remunerative expert work while the photophonic lector delivered the instruction. It is conceivable that their classes might never see them; that the name of a professor might mean to the students nothing but a sound issuing from a megaphone. From this horrible prospect I recoil. I regret the invention of the machine. I take it all back. I assure you it is all moonshine. In fact, you all know that selenium was named from Seléne, the Greek word for the moon. I confess this is all moonshine; in fact, it is only a selenium sell.

The Bullfinch Boom

Although the water-supply and railway have reached Bullfinch, and the strike has been settled, there appears to be, apart from that engendered by the unexpected arrests in connection with the Chaffinch affair, comparatively little general interest in the locality. It is now being regarded as a 'one-mine' place, and nothing, except the finding of payable ore outside the Bullfinch Proprietary, is likely to stimulate any fresh interest in the field. The Railway bill, which was rushed through Parliament during the height of the boom with such undue haste, would not have had much chance of being passed had its passage been delayed in any way pending further developments on the field. It appears that even the Mount Jackson field, to the north of Bullfinch, about which much has lately been heard, is by no means likely to become what the optimists have predicted for the place. Apart from the lack of water, a difficulty which in the fullness of time can and will be overcome, the work so far done indicates that the so-called reefs principally consist of small quartz leaders, which, although carrying fair values at the surface, rapidly become impoverished if sunk upon. It may be pointed out that the field is by no means new. It has been fairly well tested in the past; a mining township was established, the ruins of which, including a well built hotel, are still standing. The abandonment of the place appears to have been caused by not so much the lack of water as the lack of payable ore. Small working parties may perhaps be able to do fairly well here and there on this field; but the nature of the reefs appears such as to make their successful exploitation by a company impossible.—*Australian Mining Standard.*

Extraction of Gold and Silver From Slag

By E. R. Haggin

The question as to what to do with poor slag carrying gold and silver is constantly coming up, and the following method of dealing with it may be of interest. The slag was taken from a poorly-fluxed melt and assayed 112.5 oz. Ag and 2.41 oz. Au per ton. A charge of 20 kg. was ground in a small tube-mill for 12 hours, when only 5½% was retained on a 200-mesh screen; this part containing 48% of the silver and 53% of the gold, so that a good concentration of the precious metals was obtained in the tube-mill. The slimed portion assayed 60 oz. Ag and 1.12 oz. Au per ton; this was agitated for 120 hours with 0.5% KCN solution at a dilution of 2 to 1. The residue then assayed 3.2 oz. Ag and 0.06 oz. Au per ton. The extraction by agitation was 91% of the silver and 92% of the gold; the combined extraction by concentration and cyaniding being 96.6% of the Ag and 97.5% of the Au. A further improvement might be found in crushing originally in strong cyanide solution, cleaning out the tube-mill, and melting the + 200-mesh material, the slimed product going on to the ordinary slime treatment.

Geology of the Globe District, Arizona

By F. L. Ransome

*Study during the past season of the geology of the Ray quadrangle, which adjoins the Globe quadrangle on the south, has brought out some facts which necessitate changes in the stratigraphic column as given in earlier publications on the Globe district.[1] As active mining development is in progress in both quadrangles, it seems desirable to at once place this information on record for the benefit of mining engineers interested in the geology of the region.

It may be remembered that the Globe district is a veritable mosaic of small fault blocks, none of which contains a full section of the Paleozoic sediments. Consequently the supposed stratigraphic succession of the rocks was made

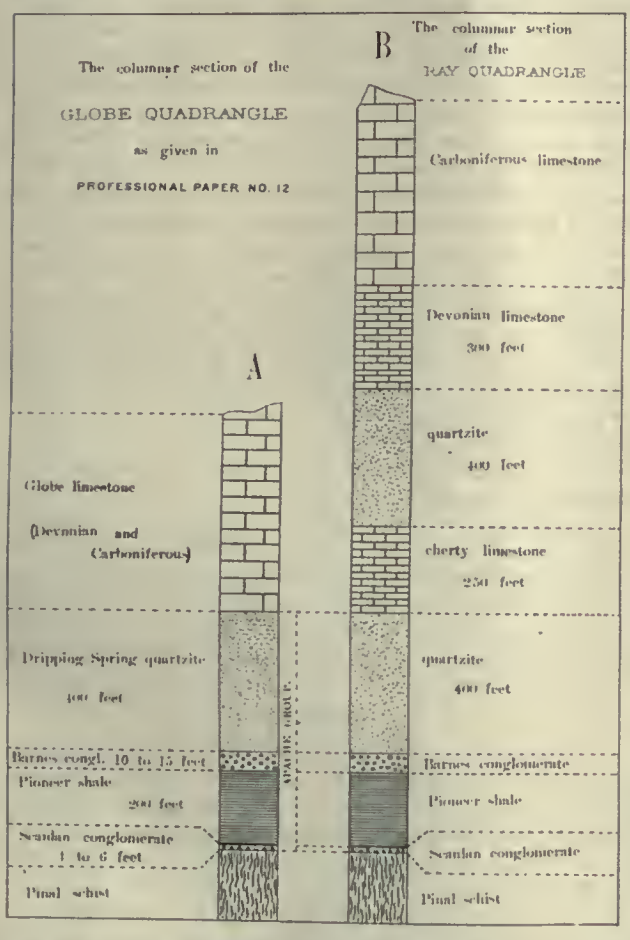

FIG. 1. DIAGRAM ILLUSTRATING THE STRATIGRAPHIC SUCCESSION IN THE GLOBE-RAY REGION.

out by piecing together fragmentary data from various blocks. Inasmuch as no single block shows more than one limestone, it was assumed that all of the limestone belonged to the Devonian-Carboniferous formation that was designated the 'Globe limestone'. Consequently, wherever quartzite was found directly underlying limestone it was supposed to belong to one formation named the 'Dripping Spring quartzite'. The stratigraphic sequence as worked out at Globe about nine years ago is given under A in the accompanying diagram (Fig. 1), in which the thicknesses given for the Ray quadrangle are preliminary estimates subject to revision. When the study of the Ray quadrangle was taken up in 1910 it was soon apparent that the interpretation of the stratigraphic data in the Globe area needed revision in some particulars. Between the Barnes conglomerate and the base of the Devonian limestone there proves to be two thick formations of quartzite separated by about 250 ft. of cherty limestone as shown under B in the diagram. The lower quartzite, for which the name Dripping Spring quartzite will probably be retained, differs from the upper quartzite in being generally thinner bedded and free from pebbles. These with other differences, once regarded as mere areal variations but now known to be characteristic distinctions, make it possible to recognize the two quartzites wherever they occur in the Ray quadrangle, and probably the identification could now be made in the Globe quadrangle also. The cherty limestone, of which a characteristic exposure is shown in Fig. 2, contains, so far as known, no fossils, and, having some resemblance to the lower, thin-bedded, unfossiliferous part of the Devonian, it is perhaps not altogether surprising that it should, in the absence of an unbroken section, have been included with the Globe limestone of the Globe quadrangle. This cherty limestone, both in the Globe and Ray quadrangles, is the formation most extensively invaded and disrupted by diabase, the limestone in some places occurring as scattered blocks in a great diabase sill or being entirely cut out by the eruptive rock. Consequently, in the Globe work the chertiness was plausibly accounted for as a result of local metamorphism,

FIG. 2. CHERTY LIMESTONE, RAY.

whereas it is really characteristic of the formation. Moreover, a reconnaissance into the Ray quadrangle while the study of the Globe area was in progress failed to reveal the true stratigraphic situation for the reason that the traverse crossed the horizon of the cherty limestone at a place where only intrusive diabase was exposed. It is easy with retrospective wisdom to say that more study should have been given nine years ago to the region around the Globe quadrangle. Since, however, economic work must as a rule be done within an estimated time, and with a limited sum of money, it may readily be understood that the unexpected intricacy of the faulting within the Globe area left little time or funds available for extensive supplementary reconnaissance.

The age of the formations below the Devonian limestone has not been definitely determined, but it is hoped that some information on this point may be obtained during the coming season. The formations between the cherty limestone and the Pinal schist, the Apache group of the Globe report, are still provisionally assigned to the Cambrian. The cherty limestone and the upper quartzite may possibly be Ordovician or Silurian. No fossils have been found below the Devonian. In the Ray quadrangle it has been practicable to map separately the Devonian and Carboniferous limestones. The adjustments in nomenclature necessitated by these changes are still under consideration. Geographic names will undoubtedly be given to the cherty limestone and the upper quartzite. The name 'Globe limestone' has no further use in its original application, and possibly 'Apache group' may also be dropped.

*Published by permission of the Director of the U. S. Geol. Survey.

[1] Ransome, F. L. 'Geology of the Globe Copper District, Arizona.' Prof. Paper U. S. Geol. Surv. No. 12, 1903. Globe Folio, No. 111, 1904.

Careful reëxamination of the Globe quadrangle would show that some small masses mapped as Globe limestone, particularly those enclosed in diabase, are really the cherty limestone. The block of limestone at the Arizona-Commercial mine northeast of Globe, for example, is composed of the cherty limestone. Here, too, doubtless belongs the block inclosed in diabase in the foot-wall of the Old Dominion mine (see Prof. Paper No. 12, Fig. 7), an occurrence that was rather puzzling when this was supposed to belong to the same general horizon as the limestone in the hanging wall. The little patch of so-called Globe limestone on the top of Barnes peak shown in Fig. 2, Prof. Paper No. 12, is the cherty limestone, as are probably most of the small areas of limestone shown on the Globe geologic map between Barnes peak and Jones gulch.

Detection of the Platinum Metals

By L. J. Curtman and P. Rothberg

*For a long time it has been known that the platinum metals present the rather remarkable phenomenon of condensing relatively large volumes of gases upon their surfaces at room temperatures, and also, that this property is especially pronounced if the metals are in that finely divided state obtained by the reduction of their salts. In 1823 Döbereiner showed that the occlusion of gases by platinum sponge, particularly in the case of a mixture of hydrogen and air, was accompanied by the oxidation of hydrogen to water, and it was noted that this reaction took place so rapidly and energetically as to cause the platinum sponge to glow intensely. From the early investigations of Döbereiner to the present day, this occlusion of gases by platinum has been the subject of much research, and, among other things, it has been shown that hydrogen in the occluded state acts in the same manner as nascent hydrogen, and that, in general, the presence of metallic platinum in the finely divided state greatly accelerates the oxidation of many oxidizable gases.[1]

Although this property of platinum has been made use of in the analysis of gases and in various commercial processes, the authors are not aware of any record which shows that the occlusion of gases and their oxidation in the presence of the platinum metals, more particularly the glow accompanying the oxidation of some gases, has been utilized as a method for the detection of platinum and its allied metals. It was the object of this investigation to determine the reliability for qualitative purposes of the 'glow reaction' obtained by passing a mixture of air and illuminating-gas over very finely divided platinum. To that end it was necessary, first, to decide upon a simple method of carrying out the reaction; second, to determine the minimum amount of each of the platinum metals that would give the test; and third, in the case of platinum, to ascertain the influence and possible interference of other substances.

Method of Making Tests.—The following method was selected, and though it may not be the most delicate or refined method possible, it has decided advantages as a practical method, because of the simple apparatus necessary and the great rapidity with which it may be applied.

The substance to be tested is brought into solution by any of the common methods, and about 0.2 c.c. of this solution is absorbed in a piece of thin asbestos paper by alternately dipping the paper into the solution and heating until the required volume has been absorbed. Experience showed the above volume (0.2 c.c.) to give the best results in these tests. The moist paper, held by one end in a pair of tongs, is now heated to redness in the Bunsen flame, then removed, and after the redness has ceased, but while the paper is still hot, it is brought into a stream of a mixture of illuminating-gas and air from a Bunsen burner. If platinum is present, the asbestos paper will begin to glow. The glow must last for some time and can be brought back after it has once died out by again heating the paper and holding it in the stream of gas. The burner must be arranged to supply a fairly good mixture of illuminating-gas and air, and the pressure must not be too great.

It is also essential, for the greatest sensitiveness of the test, that the asbestos paper be very thin. In these experiments pieces of asbestos paper 0.5 by 3.0 cm. and 0.3 mm. thick were employed, only approximately half being used to absorb the liquid. The intensity of the glow can be somewhat increased by having the gas warm. This can be easily accomplished by slightly warming the upright tube of the burner before passing the gas through it. All the results given below, however, have been obtained with the gas at room temperatures.

Determination of the Limits of the Test.—To determine the smallest quantity of each of the platinum metals that would give an unmistakable glow under the conditions of the above method, experiments were performed and it was found that the smallest amount of platinum which would give a reliable glow was 0.002 mg. The limit for palladium under the conditions of the test was found to be 0.0005 mg., while iridium requires 0.005 mg., and rhodium 0.0009 mg. Osmium and ruthenium gave negative results, probably due to the volatility of their salts. Experiments were also undertaken to determine what effect the presence of other substances has upon the test, and, in general, it may be said that all substances which, after ignition, leave a heavy residue on the asbestos paper, impair the sensitiveness of the test in so far that quantities of platinum near the limit will not glow under these conditions. Also, solutions which are acid with strong nitric acid attack the asbestos paper, swelling it up and thus also decreasing the sensitiveness of the test. It can, however, be seen from the above results that none of the common metals offer any interference to the glow tests unless present in quantities that are considerably larger than the quantity of platinum. Furthermore, the test was applied directly without going through any separations, to a sample of 'black sand' of California, to platinum residues, sweepings, and various forms of platinum waste. In each case a good test was obtained. Tests made on solutions of palladium containing respectively lead, arsenic, and sodium (the least favorable of the common metals) seem to warrant the belief that palladium will be as little affected by the presence of other metals as was found in the case of platinum.

Summary

1. The oxidation of the constituents of illuminating-gas, particularly of hydrogen, with finely divided platinum, palladium, rhodium, or iridium as catalytic agent is accompanied by a glow which is distinctly characteristic of these metals. Hence this glow may be used as a qualitative test for these metals.

2. This test is sensitive to extremely small quantities of the metals, the limits being: platinum, 0.002 mg.; palladium, 0.0005 mg.; rhodium, 0.0009 mg.; and iridium, 0.005 milligram.

3. The presence of other substances does not for practical purposes interfere with this test. In fact, the test may be applied directly to a solution without preliminary treatment for the separation of other substances.

4. In an analysis where all the platinum metals are to be considered, this test may serve to show the presence of the platinum group with the exception of osmium and ruthenium, and also to confirm the presence of platinum, palladium, rhodium, and iridium, when the metals have been separated. In most practical work, the 'glow reaction' becomes distinctly a test for platinum, the most common metal of the group. For this latter purpose the glow test recommends itself strongly, because of its sensitiveness and the rapidity with which it gives results.

*Abstract of a paper presented at the March meeting of the New York Section of the American Chemical Society.

[1] W. Henry, *Phil. Trans.*, Vol. 14, p. 266 (1824); Phillips, *Am. Chem. Jour.*, Vol. 16 p. 163.

Platinum most commonly occurs in placer deposits, in the native state, though usually alloyed with iron and frequently with copper or other metals. It also occurs as the mineral sperrylite, $PtAs_2$, associated with certain copper and nickel ores.

Slime Agitation at Kalgoorlie

By M. W. von Bernewitz

Not so long ago mill-men endeavored to make as little slime as possible, and what was made was considered a nuisance. Nowadays, however, the general practice is to make as much as possible, consequently new processes of agitating and filtering the pulp had to be devised, and are being introduced almost continually. We have the choice of the ordinary, A. Z., Kalgurli, inverted cone, Brown and its modifications, silica sponge, air-lift, centrifugal pump, and numerous other styles of agitators, each with its advantages and disadvantages. Agitation as practised at Kalgoorlie, has never been described in a general way, so these notes may be of interest to mill-men.

The following table shows how the ore is crushed and ground in our mills:

Name.	Manner of reduction to slime.
Associated	Ball-mills and pans.
Associated Northern	Ball-mills and pans.
Gt. Boulder Perseverance	Ball-mills, pans, and tubes.
Gt. Boulder Proprietary	Ball-mills, Griffin mills, and pans.
Hainault	Stamps and pans.
Ivanhoe	Stamps and pans.
Kalgurli	Ball-mills and pans.
Lake View & Star	Stamps, pans, and tubes.
Oroya Links	Stamps, pans, and tubes.
South Kalgurli	Ball-mills and pans.

The product in the dry-crushing mills will average about 87% through 150 mesh, while in the wet-crushing plants it will be over 90 through the same screen.

Each system in use calls for some little comment by way of explanation: The A. Z. agitators were introduced at the Associated mill after a long test with the ordinary type. The roasting used to be poor with some of the furnaces, and as the A. Z. agitator showed as much as 4% better results than the latter they were erected. As regards time of agitation, power consumed, and loss of cyanide, it is a case of 1 to 1½ hours, 12 hp., and 1 lb. KCN per ton, against 2 to 12 hours, 2½ hp., and about 1½ lb. KCN respectively, to which must be added the increased extraction. These vats are small, but of course the gear may be made for any size tank.

The three propeller blades are fixed on a vertical, gear-driven spindle, revolving at 60 r.p.m. The sprindle is arranged for upward and downward thrust by having ball-bearing in the head-frame, from which it is suspended. The blades are set at an angle of about 25°, and work in a 6-ft. ring, made of plate about 12 by ½ in., bolted to the bottom of the vat, and standing about 6 in. above the bottom in order to allow the pulp to circulate to the sides. Directly under the propeller, a false-bottom is bolted to the vat to prevent the sandy particles scouring the bottom. The gear and head-frame stand on 10 by 6-in. H-iron bolted across the top of the vat, and from this are suspended baffle-plates which extend nearly across. The propeller is not started until the vat is half full of slime, and it may be stopped for any time and re-started, the bottom being scoured clean. This is one good point in the A. Z.; a very sandy pulp rarely prevents its starting. When full of slime, the flow from the periphery to the centre is at the rate of about 3 ft. per second, the pulp thereby being in violent agitation, and all parts thoroughly exposed to the air. This is where the main advantage of the A. Z. lies, and other ordinary types fail. It may be thought that the consumption of cyanide would be high on account of such violent agitation and exposure to the air; but this is not so, and, providing the solution is in good order, even though the roasting is poor, it will keep up its strength well, as the following tests show:

	Per cent KCN			
At start of agitation	0.072	0.062	0.066	0.064
After ½ to 3 hr. agitation.	0.062	0.056	0.060	0.052

A peculiar point worth notice is that slime which has been agitated for four hours or so, shows at times a higher residue than that which had only one to two hours. Of course, being a gold-bearing ore, solution is effected much quicker than if it contained silver; and it was pointed out to me by an American mill-man that the A. Z. would not pay in agitating silver ore, this requiring up to 90 hours in a Pachuca tank. This is no doubt due to long contact with the air used. Would not a fast-running machine of the A. Z. type expose the pulp to the air sufficiently in a shorter time? In adding cyanide to the A. Z., it is not broken up at all, but lumps of as much as 30 lb. weight are thrown into the slime without damage to blades or gear.

A. Z. AGITATORS AT THE ASSOCIATED.

Agitation at the Associated Northern calls for little note. If the roasting and subsequent grinding is good, the agitators do good work, and an ordinary circulating solution of 0.04% KCN is sufficient for solution of the gold, this strength being made up to 0.08% before passing through the extractor boxes. At times extraction falls off, and blowing compressed air in different points of the pulp has been tried, but somehow it is not of much benefit.

VACUUM PLANT REMOVING OROYA-EXPLORATION DUMP FOR RE-TREATMENT.

The ordinary agitator acts like a buddle, in that coarse particles settle in the bottom, due to a concentration. This concentrate is shoveled out occasionally, and assays as high as $25 per ton, part of the value being in the form of fine amalgam washed over from the pans. This is dried, sent to the mills, and re-treated. The Perseverance has a very large agitation plant doing good work. The ordinary vat calls for no comment; but Mr. Wright, the metallurgist, has devised a new scheme for more rapid circulation of the slime. At an angle of 45°, from the central spindle toward the side of the vat, fixed to the stays of the agitator arms are several pipes up to 10-in. diam., with their tops almost submerged below the surface of the pulp. By the centrifugal force imparted, the pulp is forced from the bottom of the pipes to the top, and flows out in a good stream, thus ensuring that the slime at the bottom of the

vat is well mixed with the top section. Mr. Wright believes that it only takes a few minutes with large pipes to circulate all the pulp in a vat.

The ordinary practice is followed at the Great Boulder. The Hainault has devised a collecting and thickening vat, the slime from this is circulated by a Frenier special pump, and then flows over a sort of cascade for aeration to an agitator of the ordinary style, prior to filter pressing. With the ordinary type, the Ivanhoe agitates its slime with bromocyanide. Air agitation is in use at the Kalgurli in tanks somewhat similar to the Brown system, only that they are smaller, and there is no central lift. This system has been in use for nearly ten years, a considerable time before the latter came into use. The tanks are 12½ ft. deep. The first 7 ft. is 6 ft. diam., and from that point the remaining 5 ft. tapers off to 18 in. at the bottom. For the air, there are two 1-in. pipes fitted near the bottom of the tanks, and a little air at 35-lb. pressure is admitted. The pulp first boils quietly. It takes about 20 min. to fill each from the settlers, and about 20 min. to empty by means of a slime-pump which fills the presses, there being a discharge-pipe and valve at the bottom. Each agitator will deal with 24 tons daily.

The details in the following table of the Lake View & Star and Oroya Links refer to the plants re-treating old residue, using the ordinary agitator; and agitation costs are somewhat high on account of a high consumption of chemicals, etc., in treating dumps from previous wet treatment, as decomposition of minerals has set in. Most of the foregoing methods of agitation have been in operation in Western Australia for many years, and apparently give the desired results.

TABLE GIVING DETAILS OF AGITATORS IN USE

	Name	Type	No.	Size Ft.	Capacity Tons Dry Slime	Method of Agitation	Speed R.p.m.	Time Hr.	Hp.	Gear	Strength of Cyanide %	Cost Per Ton
(1)	Associated	A. Z.	6	17 by 6	22	Propeller	60	1½	12	Bevel	0.065	$0.24
(2)	Associated Northern	Ordinary	5	22 by 6	32	Ordinary arms	6	4 to 8	2½	Worm	0.08	0.26
(3)	Great Boulder Perseverance	"	24	20 by 4½	15	"	6	2	2½	Bevel	0.07	0.22
(4)	Great Boulder Proprietary	"	18	(22 by 5) (18 by 5)	40	"	6	3 to 8	2½	Worm	0.08	
(5)	Kalgurli	Air	20	12½ by 6	4½	Air		3½	2	Bevel	0.07	0.21
(8)	South Kalgurli	Ordinary	5	21 by 9	40	Ordinary arms	14	4 to 6	2½	"	0.06	
(7)	Hainault	"	3	(24 by 7) (22 by 6) (15 by 5)		Frenier pump and cascade	7	4 to 5		"		
(8)	Ivanhoe	"	11	20 by 8	53	Ordinary arms		18	3	"	0.08	0.23
(9)	Lake View & Star	"	6	20 by 6½	44	"	11	4 to 6	2	"	0.05	
(10)	Oroya Links	"	6	17½ by 9	50	"	13	7 to 8	2½	"	0.02	

Note.—Those marked 1 to 6 are in dry-crushing mills; 7 and 8 wet-crushing mills; 9 and 10 are treating old residue. The reason of the much greater capacity in agitators of the same size is due to the extra thick slime run in from the settlers, or from the dumps. The horse-power of an agitator is rather hard to determine from an engine, unless motor driven.

Simple Mine Bookkeeping

By K. C. Parrish

In small mines in the process of development where the superintendent or foreman must do his own accounting, simple forms and explanations for bookkeeping are badly needed. This has often been commented upon by the mining journals, and especially by the men actually in the field. Large properties can afford to engage trained men for this clerical work. In my experience the practical miner or young graduate, when placed in charge of a small crew of men or a small property, has some difficulty in adapting to his own use the complete and sometimes complicated systems of bookkeeping used at large properties, and such references are the only ones he is apt to find. Frequently he is not fortunate enough to obtain even these. His inquiries concerning mine accounting are generally answered by a man trained in bookkeeping, but who, not being a practical mining man, ordinarily fails to appreciate what data are most essential and the great importance of simple forms. A sense of proportion must be cultivated by the new man, who has everything in charge, so that he will not waste his time on non-essentials in clerical work.

As a result of experience and observation I have worked out some simple forms for bookkeeping for the small mine and prospect, which forms can be used and enlarged as the mine develops. For convenience, I have divided this system into three parts: (1) preliminary development; (2) development and mill installation; (3) producing stage.

Each one of these parts is arranged so as to give (A) a scheme used in the western United States, and (B) another in a remote Spanish-American country. It is only with the first, I (A), 'preliminary development,' that we are concerned in this article.

I (A)

Suppose that one man has been placed in charge of from eight to twenty men, opening up a prospect under favorable conditions in the western United States, and that he must report to a manager or board of directors once a month, besides sending a weekly letter. This man has been selected more for his knowledge of mining and his ability to handle men than for his knowledge and experience in business. He is supposed to devote most of his energy to the actual work, and not to give much time to mine accounting, especially at the expense of the work. At the same time, both he and the manager, or directors, must keep in close touch with the work, so some definite system of accounting must be used.

The following is a summary of the books needed. Those in parentheses can be omitted if necessary.

Time book.
(Development book.)
(Supply book.)
(Pay-roll.)
Cash book.
Order book.
Assay book.
Assay and development map.
(Contract book.)
(File.)
(Journal.)
(Ledger.)
Check book.

For this preliminary development no card system, loose-leaf system, or special filing system is necessary. These can be developed as may be found advisable, without confusion, as the general scheme need not be changed.

Time Book

There are several forms of time books, each having its particular use. For the mine office the style as shown is most desirable, as it is larger, giving plenty of space for daily notes. It may also serve as the pay-roll sheet.

Names	1	2	3	4	5	6	Sunday	Total time on claim	Cash	Rate	No. of shifts	Rate	Total	Amount due	Signature
Henry Miller	P 1	P 1	O	O	P 1	P 1		9 7/8 hrs 9 7/8 hrs	12 cts	—	26	3.33⅓ 3.00	85 cts	73 cts	
Wm Owens	P 1	P 1	P 1	P 1	P 1	O		8 18 5 hrs	50 cts	—	30	3.50	105 cts	75 cts	
Frank Martin	S ½	S ½	A 1	A 1	A 1	A 1	S 1	4 hrs 9 1/4 hrs	0	4 cts	28	3.17 3.00	97 cts	95 cts	
John Henry	P 1	P 1½	P 1	P 1	P 1	P 1	P 1	9 hrs	0	—	3½	3.00	96 cts	96 cts	
S Coors	P 1	O	P 1	P 1	P 1	P ½	P 1	9 hrs	6 cts	—	30	3.00	90 cts	84 cts	

FORM I. TIME BOOK.

Development Book

This may be included in the time book, by setting aside an extra double page each month. It is especially desirable in small operations, where the work is more or less temporary, to cut down the number of books kept, especially if there is no regular office. Each place worked in the mine should be represented by a letter or mark, which can be written daily in each square of the time book to show where the man works each day. At the end of the month, the number of shifts worked in each place can be counted and entered under head of 'Number of Shifts', in the development book. 'Feet Advanced' and other simple data can be entered as shown, thus giving a handy record of all the work. In cases of dispute you can tell where a man has worked each day. This can be expanded indefinitely; but in large operations it is necessary to have a separate book for such data.

	No. of shifts	Feet advanced	Total Distance	Distance from measuring peg	Total labor cost	Labor cost per foot
(d) Drift No. 1	60	40	180	50	$180.00	$4.50
(e) Drift No. 2	37	20	60	60	112.00	4.00
(s) Shaft	180½	53	120	62	540.00	10.20
(h) Hoist	90				270.00	
(b) Blacksmith	Hoist	man paid $34 extra			34.00	
(c) House	60				210.00	
(r) Roads	140				420.00	
(x) Contracts						
(v) Installing Pump	31 ⅓				95.00	
TOTAL	599	121	360		$1861.00	

FORM II. DEVELOPMENT BOOK.

Supply Book

Instead of using a separate book, a double page of the time book may also be set aside each month for a supply book, as shown. Time books are large and cheap, and with the data thus concentrated there is les sdanger of loss. An invoice of all ordinary supplies should be taken on the first of every month, and written in the supply book. The supply account should be kept not only to ascertain the amount of supplies used, but to stop any leaks, and to find out what supplies will be needed, so that there will be no shortage and expensive delays. On careful perusal the form shown will be self-explanatory; it may be reduced or enlarged as desired, and will show the approximate cost of supplies as needed in handling the work. The accounts in the time, development, and supply books, as outlined above, are primarily for the use of the man in

FORM III. SUPPLY BOOK.

charge, but as the average man will not keep up these cost tables for his own benefit, it is important that a report of costs should be required each month.

Cash Book

A cash book, properly ruled and headed, will give the directors and the home office most of the desired information. The figures from the cash book are kept in the home office, and from them the annual cash statements and reports are made. This form of cash book makes it unnecessary to keep accounts in ledger form with different parts of the work, and hence saves a large amount of bookkeeping. I will describe its use in detail, even at the risk of explaining that which may seem obvious. The study of this cash book will amply pay for the effort required.

First, select your headings; be sure that they are what you want, and do not try to start with too many. The idea of this kind of cash account is, that when, for example, a bill is paid, the total is put under 'credit', as in the ordinary cash account, and, at the same time, this bill is subdivided and the amounts put down under their respective heads, as 'Mine Supplies', 'Power', 'General Expense', etc., as in the examples given.

As a rule, payments on account of labor are not entered in the cash book until the end of the month, as it is not convenient to divide labor costs during the month. For convenience, each of these subheadings in the cash book is lettered, so that at the end of the month, or when the pay-roll is made out, these letters can be used on the time book or pay-roll, to indicate under what heading the payment should be placed, so that they may be easily transferred to the cash book, either in detail or as a whole. The column marked 'Transfer to Cash Book' in the time book contains the segregations of the labor costs which are to be entered in the cash book. It is not necessary to make out this pay-roll separately from the time book, and not at all, as far as the payments to the men are concerned. When the work assumes large proportions, it is made out to more carefully divide the labor costs, and to have a more complete record of such a division. This extra pay-roll can be made out in either of two ways: the workman's name appearing on the pay-roll the same number of times as the number of headings under which his work comes; or the workman's name is only written once, but there are as many columns as there are divisions of labor in the cash book.

Before bills are filed away, and at the time they are paid, and the amounts entered, and divided on the cash book, a note should be made on them showing the segregations. These can be used for reference.

At the end of the month all the money received would be listed under 'debit' and all the moneys paid out under 'credit'. The difference will be 'cash on hand'. The sum under 'credit' must equal the sum of the totals of the columns marked (a), (b), (c), etc., and for this reason the cash statement can be made out at the end of the month as shown in Form V.

Form V

Cash Statement of 'The Mutual Mining Company'
For the Month of..... 19....

Jan. 1—Balance on hand.....	$1230.46	
" 8—Draft 4/1/11 from Chicago..	2500.00	
" 31—Mine labor		$ 832.00
Surface labor		304.00

Construction and machinery..		1580.68
Mine timber		170.00
Power		208.00
General expense		14.60
Superintendence		295.00
Feb. 1, 1911—Balance on hand.....		226.08
	$3730.46	$3730.46

Cash books ruled for this kind of work can be purchased at any good supply-house. The same is true of the large-sized time books and pay-roll. If cash is handled at the mine, it is always convenient to keep a small note-book with the cash, in which to enter all cash paid out. Payments of bills are checked off in this note-book when entered in the cash book. This applies also to money advanced for labor or merchandise when charged on the pay-roll or ledger. With this little book, the cash is checked up. A check book answers the same purpose and is preferable when it can be used.

CASH STATEMENT of the MUTUAL MINING CO. NEVADA. for the Month of 1911

FORM IV, CASH BOOK.

Order Book

For small operations this is only a memorandum book to keep track of the prices of supplies; to make note of the supplies needed, and other information pertaining to them.

Assay Book

Every assay taken is numbered and the number entered in this book with a full description of the sample and where it was taken. At least a couple of lines should be

left between samples so as to put down results. In small operations no other book need be kept for assays.

Assay and Development Map

This map should be drawn on a scale of from 20 to 40 ft. to an inch. This does not come under the head of accounting, so it will not be discussed in detail, but it is a part and not the least of the clerical work the superintendent must perform. It must be remembered that the real object of the work is to determine the size, extent, and value of the ore, so this is more important than accounting and comes first. It pays to have a good map of the mine workings, both in plan and vertical projection, placed on a table where it is easily accessible at all times, as it is from such maps that the ideas for future work are gathered and digested. Upon these are written the assay-value and width of the veins or stringers at the proper points, cross-veins, faults, and dikes. This information should be brought up to date every month, no matter how rough the monthly survey may be, or how poor the draftsman. It is to obtain this information that the mine is being developed, and adequate records must be kept of it. This is the best way for every purpose.

Contractor's Book

In this book all data pertaining to contracts should be kept; however, if the number of contracts is small, they can be noted in the development book, assay book, or ledger.

Journal

In the journal all daily transactions are recorded, buying, selling, or receipt of wood, timber, lumber, etc., and they are checked off only when they are entered in the ledger or paid.

Ledger

A ledger account is kept with all persons with whom business is done regularly. Ledger accounts are not ordinarily necessary in small operations, as the labor will be kept track of in the time book, pay-roll, and check book, or the cash 'memo' book, and the bills show the accounts with firms. The petty accounts show in the journal.

File

This can be any ordinary index file, in which all bills that have been paid can be filed away according to the name. There are a great many good systems of filing, especially those which eliminate the journal and ledger work, but I do not think the small mine need bother with such refinements. The bill file can be eliminated in preliminary work, especially when some one checks up the monthly bills and statements, by simply putting in one large envelope all the bills that have been paid and notes pertaining to them for that month, so that the bills for each month that have been paid are kept separate. In this manner the accounts are easily checked. Keep copies of every letter, statement, and bill sent to the home office.

Check Book

This does not need special explanation. Do not neglect to number all the checks issued and to keep the balance on hand to date on the stub of the check book. Have your bank render a statement of your account just before payday, and return the paid checks, which serve as receipts in case of dispute.

Summary of the Month's Work and Cash Statement

Cash book.
Pay-roll (from time book).
All bills and letters pertaining to same.
Check book, showing balance.

With these the monthly cash statement is made out. (Form V.)

Supply sheet.
Order book.
Disputed bills and letters pertaining to them.

With these he writes his agent or merchant, giving orders for supplies, and answering or asking questions.

Development sheet.
Supply sheet.
Assay and development map.
Notes on cost of work and supplies.

From these, together with the cash statement, he gives his observations and extra data on costs per ton per foot developed, work done and plans as to future work, being careful to distinguish between what are known facts and what are only surmises and indications.

Tungsten Deposits of Stevens County, Washington

By L. K. Armstrong

Tungsten was discovered in Stevens county, Washington, about five or six years ago, in Cedar Canyon district, 25 miles west of Springdale. Since that time mining has been carried on intermittently, shipments of concentrate having been made to Germany. For a time there was litigation and operation at a loss, but recently legal questions have been settled and capital has been obtained to put in an ore-dressing plant, and the mine is being operated at a profit. These deposits occur in quartz veins in granite and extend southwesterly to the Spokane Indian reservation. The mineral is wolframite.

Northeast from Springdale about 12 miles, and about 12 miles north from Deer Park, is another locality where tungsten occurs. This occurrence is even more interesting than that at Cedar Canyon, as it is found where the granite has intruded through the sedimentary rocks, in both of which the tungsten mineral hübnerite is found. Work here has thus far been confined to a section of land the title to which is vested in the State, and leases on a 5% royalty have been obtained. The strike of the contact near which operations have been conducted is nearly southwest. Operators on the northeast quarter of the section are working in the granite, while those on the southeast quarter are working in the sedimentaries, each driving toward the contact. Operations up to this time have not been continuous, nor concentrated at one point. To the north the ore occurs in the granite as replacing the original minerals which were doubtless somewhat shattered along the line of contact at the time of the intrusion. So far as I am aware, there is no other mineral than hübnerite in the granite. On the south side of the contact, in the shales which have been split and broken along the line of fracture to some distance from the intruded rock, there is a series of quartz veins which have formed in the bedding planes of the sedimentaries at several points of fracture which carry rich deposits of hübnerite in bunches and short shoots; and isolated from these are pockets and streaks of a bismuth mineral which has been designated by the U. S. Geological Survey as cosalite. An analysis of this made at the laboratory showed 45.25% bismuth, 33.66% lead, 16.58% sulphur, 0.80% silver, 1.16% copper, the balance being gangue and moisture. Pyrite, hematite, and limonite are found both in the veins and the adjacent shales.

Some interesting legal questions may arise when mining from the north and south shall have reached the contact of these rocks, although, title having passed to the State previous to the discovery of mineral, the law of apex cannot be applied. Something like 3½ tons of concentrate, carrying over 60% tungsten trioxide, was marketed from one of these properties some months ago, for which they were paid $8.50 per unit of 20 lb., f. o. b. Denver. The ore was obtained from a vein in open-cuts and a shaft in the shales, and was milled on the ground. Specimens of hübnerite have been exhibited which are said to have been found 5 to 10 miles to the northeast of the last-named locality, and if the statements prove correct the belt will have a total length, from east to west, of 40 to 50 miles. The field is a good one to investigate and will be likely to develop some good mines.

The Matabichouan River Power Development

By Franklin Thomas

*The streams of northern Ontario, with its rugged topography, abound in water-power, but the development of these sites would not be justified, in the majority of cases, because of a lack of market for the power. With the discovery of silver at Cobalt about six years ago, and the subsequent development of mining operations, there arose a demand for power. For several years each mining plant provided its own power supply as best it might, usually with high cost of equipment, and invariably high cost of operation, and often with unsatisfactory results. A large part of this power was consumed in driving air-compressors, the compressed air being used to operate rock-drills, pumps, and hoists.

With the growth of such a favorable market for power it is natural that the adjacent water-power sites should be regarded as furnishing the solution of the power problem. Accordingly the Mines Power, Ltd., was formed with E. A. Wallberg, of Montreal, as president, to furnish both electric power and compressed air to customers in this district, this power to be generated at a hydro-electric station on the Matabichouan river, about 23 miles south of Cobalt. A development with a normal output of 8000 hp. has been made at this place, which is the largest available site within this radius. With individual mines generating their own power, the cost ranged around $150 per horse-power, while the electric power is sold at $50 per horse-power per year, and the compressed air at $60 per horse-power.

The power-site on the Matabichouan river was admirably adapted to economic development. As shown on the accompanying map, the Matabichouan river serves as a connecting link for several adjoining lakes and finally drains the Bass lakes into Lake Temiskaming, which in turn feeds the Ottawa river. Almost at the outlet of the First Bass lake the river commences a descent of nearly 300 ft. in a succession of rapids, the course of the stream meanwhile describing a bend and doubling back so that the foot of the rapids—which is two miles from Lake Temiskaming—lies not far from a bay of the First Bass lake, but on a lower level. The construction work was done by E. A. Wallberg, with J. R. Nichols as superintendent. Messrs. Smith, Kerry, and Chase, of Toronto, made the designs, and members of their staff acted as resident engineers.

The flow of the river is extremely variable. In May and June, after the spring thaws and rains, it develops into a flood, while in September, before the fall rains, and in March, before the spring water, the minimum flow of 90 second-feet, equivalent to about 2000 hp., is reached. This condition necessitates the construction of an extensive storage system, which will be referred to later. At full load the turbines require a total of 365 second-feet. By constructing a dam, which raised the level of First Bass lake about 40 ft., the head-water is brought up to the brow of the hill leading to the foot of the rapids. This also furnishes additional storage, giving a good operating margin at the plant.

A canal 800 ft. long and 20 ft. wide, submerged at the new lake level, providing a channel for the head-water with a uniform depth of 20 ft., leads up to the intake, where the water passes into two steel pipe-lines, each 5 ft. diam. The pipe-lines are 1200 ft. long and pass under the floor of the power-house. The power-site lies within a timber limit owned by the Shephard & Morse Lumber Co., of Ottawa, and in an unsettled region, so camps had to be erected to house the workmen, the site cleared of timber, and transportation of material and plant provided for. Operations were begun about June 1, 1909, immediately after the close of the log-drive. While the site was being cleared, supplies were brought up by rail to Temiskaming, on the Canadian Pacific railway, at the foot of Lake Temiskaming, 40 miles from the work, and transferred to scows, which were drawn by steam launches to the foot of the rapids on the Matabichouan, near the site of the power-house.

A railway was constructed, leading from the scow landing to the foot of the hill, near the power-house site, then up an incline 1400 ft. long to the upper level, and half a mile farther to the site of the main dam. Horses furnished the motive power for the railway, except on the inclined portion, which was operated by a hoisting engine and cable. Nearly all the supplies and materials necessary were brought in before the close of navigation, about December 20. After the close of navigation, a good winter road was made, for the most part across lakes, to Temagami on the Temiskaming & Northern Ontario railway, eighteen miles distant.

Sand for concrete was obtained near the mouth of the river on the shore of Lake Temiskaming, while a quarry and crushing plant near the site of the dam, supplied the greater part of the crushed stone required. Approximately 40,000 bbl. of International portland cement was consumed in the various structures. The laborers employed included French Canadians, who were used mostly on the clearing, crib-work, rough carpenter work, and concreting, Italians for excavation, and Indians from the Caughnawaga Reserve near Montreal for trestle-work, steel-work, handling machinery, and concreting. These last were especially good in general work as a result of their experience in a structural works near their reservation. The summer of 1909 was required to clear the site of the operations, to make excavations, and to set up the necessary plant.

In order to clear the surface of the bedrock for the dam in the river bed, about ten feet under water, a crib dam was built, which would carry the natural flow of water along the river bank and discharge below the crest of the rapids so that it would not run back and interfere with the excavation. With this arrangement the river section of the dam was put in, then the sluice closed and the water held back while the sluice was torn out and this section of the dam brought up temporarily out of reach of the water.

The main dam rests upon a solid rock foundation throughout, abutting against the rock at the east end and penetrating a gravel and clay bank some 30 ft. at the west end. A trench 1 ft. deep and 2 ft. wide was made in the bedrock to give a bond with the concrete. The rock was thoroughly cleaned and washed, then grouted before concreting in any section was commenced.

The dam, which is of solid concrete, has a top width of 2½ ft., the top being 3 ft. above high-water level, with a down-stream batter of 1 in 2, and an up-stream batter of 1 in 12. The length of the dam is about 700 ft, and in the river bed reaches a total height of 53 ft. Expansion joints occur at 50-ft. intervals, and this furnishes a convenient unit for pouring. The regulating section comprises three waste sluices 14 ft. wide, draining 12 ft. below high-water level, and a long sluice 20 ft. wide and 8 ft. deep. The sluices are separated by piers which support a reinforced-concrete deck. Drop-logs of 1 sq. ft. cross-section, handled by winches, serve as gates. West of the regulating section is a spillway 50 ft. long at the high-water level.

The concrete in all the structures was 1-3-5, and was mixed as wet as practicable. Large stones varying from one-half to a cubic yard in volume, were freely used as displacers in the concrete. These were obtained from the quarry, and deposited so as to be not less than 1 ft. apart. A 4-ton cableway 800 ft. long was erected over the centre-line of the top of the dam, and proved very useful in aiding excavation, and in subsequent handling of forms and displacers. The mixing plant for the dam consisted of two half-yard Ransome mixers, fed by gravity from bins which were kept stocked by cars of materials hauled up an incline. Water was pumped to a tank on a level with the bins. With this arrangement, each turned out two mixes every five minutes. The concrete was conveyed to place by 1-yd. steel dump-cars, running on a double-track trestle along the up-stream side of the dam. There was a slight grade in favor of the loaded cars. Hoppers were placed at inter-

*Abstract from *The Transit*, University of Iowa.

vals along the trestle; from these, by swinging chutes, the concrete was deposited as desired. The concreting operations were carried on throughout the winter of 1909-1910, work being suspended only on a few occasions of severe cold. Steam-coils were placed in the bins feeding the mixers, to heat the water. With this arrangement zero weather presented no serious obstacle. After pouring stopped in any section, the forms were covered and live steam turned into the forms.

The main dam backed up the water on the four Bass lakes and on Trout lake, an area of 2 sq. mi. Above these lakes, the river follows a narrow channel to the outlet of Rabbit lake, nine miles from the main dam. At a convenient location here, as shown on the map, a crib dam was built, capable of storing 13 ft. of water on this lake,

MAP SHOWING MATABICHOUAN RIVER POWER DEVELOPMENT.

which has an area of 8 sq. mi. The dam is provided with three regulating sluices with drop-log gates. The other cut-off dams were constructed on other bays of the lake, only one of these being provided with a sluice, which permits the flow of water either through the river channel or through Ross and Cooper lakes. To take advantage of the latter condition, an old logging-dam at the outlet of Cooper lake was rebuilt, giving several hundred acres additional storage.

The Rabbit lake dam is capable of backing the water up to the outlet of White Bear lake, where a dam, similar to the main dam on Rabbit lake has been constructed, capable of storing 8 ft. of water on White Bear lake, an area of 4 sq. mi. This dam is 10 mi. by water from Rabbit lake dam. Attendants are stationed at the Rabbit lake and White Bear lake dams. These dams furnish ample storage for present requirements, but should it prove necessary, there are one or two other storage areas which might be utilized. The total drainage area tributary to the plant is 350 sq. mi., but the total run-off could not be retained, owing to the immense quantity of water required to float logs through the numerous rapids of the Matabichouan. Nearly 500,000 logs pass through the river and the main dam annually.

The intake consists of two forebays, each 8½ by 15 ft. behind the drop-log gates. At the high-water level there is 20 ft. of water over the mouth of the penstocks, one of which leads from each forebay. These are 1200 ft. long, 5 ft. diam., and reach the power-house by four grades of nearly equal length, increasing toward the power-house. The pipes are spaced 11½ ft. c. to c. at the upper end, and 10 ft. at the power-house, and supported by concrete saddles spaced 12 ft. apart along the pipes. The penstocks were supplied by the Jenekes Machine Co., of St. Catherines, Ontario, and were shipped in 12-ft. lengths. The plate varied in thickness from 5/8 in. at the power-house to 3/8 at the top. At high-water the total head is 317 feet.

The power-house is of reinforced-concrete throughout, 60 by 110 ft., containing four Francis type turbines direct-connected to rotating field generators, and two Doble wheels direct-connected to the exciters. Two turbines and one exciter wheel are run on each penstock. The turbines are single runner wheels with side-discharge, designed for 2750 hp. maximum, fitted with 25-in. gate-valves to shut off the wheel-cases, and controlled by Jens-Orton-Boving governors. The generators are 1875 k.v.a., 2400-volt, 3-phase, 60-cycle machines running at 600 r.p.m. The exciter wheels are controlled by needle-valves. Each exciter is rated at 100 kw., 800 amp., 120-125 volts, and is capable of exciting all four generators. The four transformers, 1875 k.v.a., 2400-44000 volts, 3-phase, 60-cycle, are water and oil cooled. A storage battery with a capacity of 80 ampere-hours is provided for emergency uses, to furnish power for the electrically operated switches, and to be available for lighting purposes.

The transmission line is double, 24 mi. long, of No. 0, 7-strand, aluminum cable. A telephone line runs along one pole line, the wires being transposed at every third pole, and a telephone transformer is placed at each station to counteract induction effects. The voltage is higher than customary for the present distance of transmission, to allow for a possible extension of the line. Effort was made to get the plant in operation as early as possible, and the wheels started after an interval of slightly more than nine months had elapsed since the first clearing on the site had been made.

There are sub-stations at Cobalt, Brady lake, and Beaver lake, the two former containing air-compressors, and the latter transformers only. In each of the compressor stations there are two 1000-hp. motors driving separate two-cylinder air-compressors. The air coming from the first compressor is under a pressure of 45 lb. per square inch, and comes from the second at 110 lb. pressure. The air then passes to the drying chamber, where the moisture is removed, which prevents freezing in cold weather. From the stations, the air is delivered through 10-in. cast-iron mains, carried on the surface of the ground to the users at the various mines. The Cobalt and Brady lake stations are ten miles apart and two pipe-lines are connected so that one station may relieve or supplement the other. In addition to compressed air, electric power is distributed from the sub-stations. The service given has been very satisfactory, and has greatly reduced the cost of power in mining.

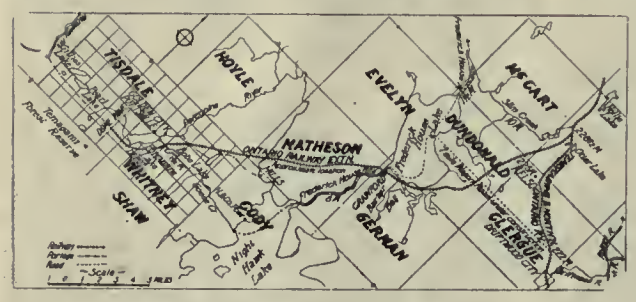
PORCELAIN INSULATORS are formed in plaster or steel molds from a plastic mixture of finely pulverized clay, feldspar, and quartz. After being dried and glazed they are burned in potters' kilns. The clays used are the white clays which are found only in mountainous regions. The body-mix for these insulators is of the same sort as is used in china dishes. Some insulators have been made from such fire clays as are used in the manufacture of stoneware, jugs, and crocks, but these have not so high a dielectric strength as may be obtained in the artificial porcelain mix. The composition of insulator bodies is not as important a factor as the development of dielectric strength of clay insulators as is structural density, and it is for this reason that in some cases insulators of high dielectric strength have been lathe-turned from some of the fine-grained rocks, such as the soapstones.

The Porcupine Gold Area

By Ralph A. Meyer

Until the last two or three years the Porcupine area was difficult of access and little prospecting was done. Practically all the information concerning it was contained in the reports published by the geologists who accompanied Mr. Niven, the Ontario land surveyor, in his base-line work, and the township surveyors in the years 1896-9 and 1903-5. The first real prospecting in the area was performed in 1906 on the Wilson claim now known as part of the Timmins mine. In 1909, during the month of June, interest was revived in the district by numerous discoveries, following which a brief examination and report was made by James Bartlett, one of the Government geologists. Since then approximately 10,000 claims have been staked.

The greater amount of development has been performed in Tisdale township on such properties as the Timmins, Dome, Foster, Vipond, Crown Chartered, and Armstrong-McGibbon. But there are several properties in the adjoining townships, namely, Whitney, Shaw, Deloro (formerly known as the Temagami Reserve), Carmen, Langmuir, El Dorado, and Denton, among others, where phenomenally rich surface showings have been discovered.

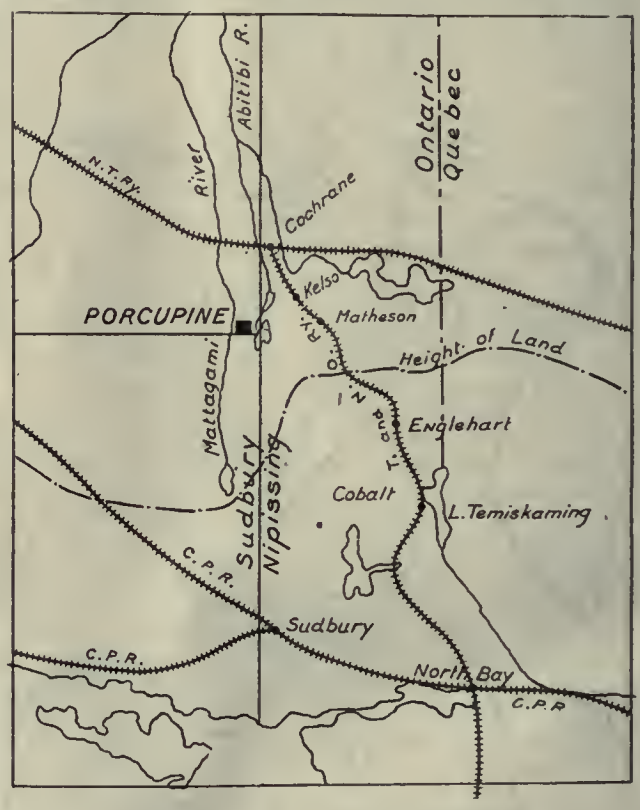


RAILWAY EXTENSION TO PORCUPINE.

These claims have been purchased for large sums of money and are at the present time being actively developed and prospected. I wish strongly to emphasize the fallacy of the general belief that all the 'pickings of the pie' are in Tisdale township. It does not follow because the Ontario Government has decided that each township shall be six miles square that mineral occurrences cease at the approach of a division line. The unitiated are prone to regard those lines as stone walls. The public should not be too easily captivated by spectacular free-gold showings. The required tonnage will be obtained from the sulphide deposits; and in my opinion there is no doubt even at the present early stage that the necessary tonnage exists. Both the Dome and the Timmins properties are erecting mills of 40 and 30 stamps respectively, equivalent to a daily capacity of approximately 350 tons. Several of the smaller properties, as well as those that are in earliest stages of development, have and are constructing small mills. I personally believe that certain parts of the district will develop the greatest free-milling ore mines in the history of gold mining on the North American continent.

Porcupine may be reached by driving a distance of 34 miles from Kelso on the Temiskaming & Northern Ontario railway. This is known as the winter route. During the summer and spring months, the journey has been performed by driving and launches. The first portion of the journey is a 12-mile drive; 7 miles on a fairly good Government wagon-road, and 5 along the shore of Frederickhouse lake on a gravel bed, to what is known as Crawford's stopping place, at the junction of Frederickhouse lake and the Frederickhouse river. From this point gasoline launches run up the Frederickhouse river, across Night Hawk lake in a northwesterly direction to what is known as Hills, a distance of approximately 14 miles. From this point, the journey is completed by driving on the Government road to Porcupine townsite, better known as Golden City, a distance of 8 miles. Both during the summer and winter months the total journey from Kelso to Porcupine can be made in a day, and during the winter season, it takes a considerably shorter time, as the entire distance is traversed in sleighs.

The Ontario Government is at the present time extending the railway from Kelso to Porcupine, the road has been completed and trains are already running to Frederickhouse. The Government expects to have the entire track laid by the end of June of this year. Even under present conditions one is able to reach Kelso, within 34 miles of the camp, from New York in a Pullman car, the journey being completed within 1½ days. In the history of gold mining in America, such easy access to a gold camp from the large centres, such as New York, Chicago, Pittsburg, Boston, and Toronto, has never been known before. This is important, as those who invest appreciable sums of money in Porcupine are in the position to make frequent visits and keep in touch with their various enterprises more satisfactorily than if the seat of operations were remote, in Alaska, for example.



MAP SHOWING SITUATION OF PORCUPINE.

There are three townsites, all on Porcupine lake (which is approximately 2 miles long, ½ mile wide, and 913 ft. above sea-level). The townsite known as the Provincial, or Golden City, is at the extreme north of Porcupine lake; that known as Porcupine, where the greatest amount of activity has so far been displayed, is at the extreme northwest side of the lake. Since the location of the railway has been definitely decided upon, there is no doubt that the Provincial townsite and the one at the extreme south end of the lake will be the most active ones, as there will be a depot at each of them. The Recorder's Office and several stores are at Golden City. A postoffice and hotel known as the 'Shuniah,' as well as two banks are in Porcupine.

At the time of writing, three other hotels are under construction in addition to a postoffice and theatre at the south end. There are already five banks in the camp. The townsites are all on flat country partly composed of 'muskeg' (a local term designating swampy ground). The camp is connected with the outside by telephone; two lines are in operation, one to Kelso and the other to Matheson. The former is operated chiefly for local calls, while the latter is used mainly for the forwarding of telegrams. The telephone system is controlled by a private company.

At present the properties have to generate their own

power, but such will not be the case nine months hence, as a syndicate has leased Sandy falls, on the Mattagami river, in Mountjoy township, six miles distant from the centre of operations. Two 3000-hp. units will be erected, enough to supply electric power for operations as well as motive power for the generation of compressed air for the entire camp.

The greater part of the surface area is low and wet; this considerably hampered prospecting last summer. But about a dozen valuable discoveries have been made in the so-called swamps since the freeze-up. There is no doubt that as soon as mining operations are in full swing, these swamps will be drained, as the water is only surficial. The rock surface is occupied by a well-banded clay, together with some sand and gravel. Overlying the clay is a layer of vegetable mould, from a few inches to a foot or more in thickness. Outcrops of compact rock occur irregularly, somewhat resembling the undulated surface of a calm sea.

Since some of the outcrops are small they are difficult to detect. In some sections the rocks rise into ridges or dikes, which extend across several claims. In most cases the rocks do not rise to a greater height above the general level than 50 ft.; rarely to as much as 100 to 150 ft. the area lying between the mouth of Porcupine river and Porcupine lake has a maximum elevation of about 970 ft.; the southwestern portion of Tisdale is considerably higher, reaching an elevation of 1000 ft. The lakes are narrow and the rivers have cut deep. The greatest depth of Porcupine lake has been found to be 20 ft. The oldest series, the Keewatin, is like the rocks of this age found in various parts of the province of Ontario from the Quebec boundary on the east to Manitoba on the west. The series is here much more disturbed in many places than it is in the Cobalt area. Some of the Keewatin rocks have escaped dynamic metamorphic agencies sufficiently to show their general character. Most of the Keewatin in the Porcupine area as elsewhere, consists of dark colored or greenish schistose rocks of basic composition. Quartz porphyry is quite a common rock. While it occurs characteristically in dikes it is also found in large masses. Associated with the Keewatin, especially in the southern part of Whitney township and southeastern portion of Shaw, there is much iron formation. This iron formation is what is known as 'jaspilite,' consisting of thin alternate bands of magnetite and silica. In certain instances the Keewatin rocks contain calcite, dolomite, and other carbonates.

A belt of Huronian fragmental rocks outcrops at various places in the northern part of Whitney township and southwest through Tisdale township. It has been subjected to great metamorphism, and in some instances has been rendered highly schistose. Several dikes of olivine-diabase, cutting the Keewatin have been found in the area. Both serpentine and sericite-schists occur, being mostly associated with the quartz-porphyry and rhyolite. Some of the schists are impregnated with pyrite and ferruginous dolomite, which at the surface cause the rocks to weather to a rusty-brown color, due to iron oxide. The general strike of the schist is northeast. There is pronounced evidence of glacial action over the entire area.

Outcrops of quartz are numerous. They are found both in the Keewatin and Huronian. The age of the rock does not seem to have any bearing on the character of the vein, either as to form or to gold content. The quartz deposits of the Porcupine area are probably connected with the great granite intrusions which took place in post-lower-Huronian times. The quartz has been deposited from the impure waters, highly heated and under great pressure, which worked through the rocks after the granite intrusion. The veins vary in width from a few inches to 30 and 40 ft., the average width being about 3 to 4 ft. In many instances the orebodies cut across the strike of the schist; in such cases they vary considerably in width from point to point. In individual cases masses of quartz 75 to 100 ft. in width occur, which are rich in free gold.

A feature not to be overlooked is the persistence of the veins, which in the majority of cases can be traced for hundreds of feet, and in individual cases for thousands of feet; both hanging and foot-walls are exceptionally well defined. The area over which these veins occur is very extensive (covering an approximate acreage of 50 sq. mi.), and is likely to be largely extended by future discoveries.

California Oil Production

The April output of California oil wells, according to figures compiled by the *Oil World*, was 6,544,128 barrels, which is a gain of 406,080 bbl. over that of March. This is exclusive of 399,674 bbl. of oil consumed as fuel in connection with operations in the field. In the following table is given, in barrels, the production by districts for April and March:

District—	April.	March.
SAN JOAQUIN VALLEY.		
Coalinga	1,382,770	1,516,320
Kern River	1,076,000	1,048,300
Maricopa	389,380	279,605
Midway	1,677,700	1,633,442
McKittrick	419,300	475,300
Total	4,945,150	4,952,967
COAST REGION.		
Santa Maria-Lompoc	699,916	535,000
Summerland	5,410	5,607
Total	705,326	540,607
SOUTHERN FIELDS.		
Salt Lake-Sherman	237,325	245,904
Los Angeles City	36,500	37,000
Whittier-Coyotes	93,941	86,225
Fullerton-Puente	476,045	432,500
Newhall	11,240	11,900
Ventura	37,601	34,500
Total	892,652	848,029
Grand total for State	6,543,128	6,341,603

Kalgoorlie, Western Australia

During March this State produced $1,792,000 in gold. The yields from the principal mines were as follows:

Name.	Tonnage.	Yield.	Profit.
[4]Associated	[1]5,435	$ 60,500	.....
Associated Northern Blocks.	1,261	18,500	.....
Bullfinch Proprietary	230	39,000	.....
Chaffers	3,435	22,500	$ 170
Golden Horse-Shoe	26,377	185,000	17,500
Golden Ridge	2,763	32,500	15,000
Great Boulder Perseverance.	20,344	144,500	41,000
Great Boulder Proprietary..	18,221	240,000	120,000
Great Fingall	10,606	77,500	11,500
Hainault	4,870	34,500	3,750
Ivanhoe	10,104	20,500	90,000
Kalgurli	10,820	115,000	52,500
Lake View Consols	[2]8,142	8,500	2,400
Lake View & Star	13,314	82,000	[3]6,000

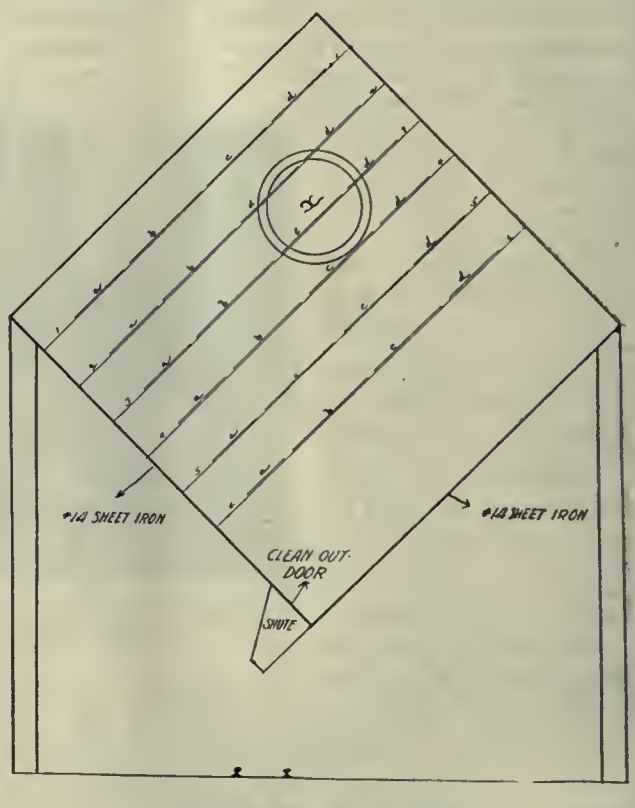
Dust-Collecting System

Dust gives rise to many problems in and around mills. Entirely aside from the health of employees, a question sufficiently serious to warrant attempts to correct the evil, dust is injurious to machinery, and decreases output, since men will not work at full vigor continuously in the dust. In American mills relatively few attempts have been made to collect and settle the dust, presumably because dry-crushing is no longer common. At the old or No. 1 mill of the American Zinc Extraction Co., at Leadville, a dust-collecting system was built. The following description is based upon notes and a sketch furnished by C. A. Lemke, superintendent. The crushers and other machinery were housed-in and connected with exhaust fans and a settling-chamber. Two No. 35 B. F. Sturtevant centrifugal exhaust fans with 13-in. intake opening and outlet of the same size were used. The pipes connected with the intake of the fans were made of 26-gauge galvanized iron, the joints being riveted and soldered. The fans were placed on the top floor of the mill, and these 13-in. pipes ran vertically to the basement. Smaller pipes, ranging in size from 3 to 5 inches in diameter, and made of the same material, were connected at one end with the main pipes, and at the other with the feed-boxes of the separators, with the conveyor housings, with the heads of the elevator housings, and with the automatic scales. All joints were made air-tight by riveting and soldering. The pipes connected to the exhaust end of the fan were of the same material as the intake pipes, and led into the dust-chambers, where the dust was collected. These chambers are about 120 ft. long, with a stack 18 inches in diameter at the end farthest from the fan. They are shaped as shown in the sketch below and contain baffles about 12 in. apart. The dust was caught by these baffles and, as they are inclined at a steep angle,



DUST-COLLECTING CHAMBER.

it slides off them into the bottom of the chamber, where it is scraped out by hand into a small mine-car and trammed to a dust-bin.

The Mololoa Mines

STAFF CORRESPONDENCE

The Mololoa mines in the Hostotipaquillo district of Jalisco, famous *antiguas* of western Mexico, have been purchased by Makeever brothers, of New York, who are now operating in the Hostotipaquillo and San Sebastian districts of Jalisco. The Mololoa Mining Co. is being organized to take over and operate the properties, and a mill will be erected within a year. The Mololoa mines have an interesting history. They were opened by the Cora Indians some time before the Spanish occupation. When the Spanish invaders reached that part of Mexico their fame was such that Gines Vasquez del Mercado, the Spanish captain, sent to pacify the Coras, was disappointed at not finding a mountain of practically pure gold and silver. Among his followers, however, were men more easily satisfied, and they eagerly continued the work started by the Indians. Old records show that in the seventeenth century the mines passed into the possession of one Tomas Treviño, and a partner, who also acquired mines across the Santiago river, some distance north. For purposes of communication they established a system of fire signals between the two camps. Treviño worked the Mololoa mines with such success that he aroused the envy of other Spaniards who conspired to get possession of the properties. With his fire signals as evidence, they accused him before the Holy Inquisition of practising diabolical rites, and he was taken to Mexico City, tried, convicted, and burned to death in 1645. His partner secured what he could hurriedly, wrecked the mine workings, and escaped from the country through the port of San Blas. The Mololoa mines were reopened in 1904, after a long period of idleness, and since that time have yielded much rich ore. A fault interfered with operations for a time, but last year the vein extensions were found and the rich ore-shoot re-opened.

Production on the Rand

The March gold output of the Rand, amounting to 676,056 fine ounces, valued at £2,871,740, constituted another record, but even this will be passed as soon as the mills recently erected at Randfontein, City Deep, Roodepoort, and Bantjes can be put on anything like full production. It was known that the East Rand Proprietary mines were in temporary trouble over the repairs to the Angelo shaft, and that it would cost them, for at least one month, the credit hitherto enjoyed of being the premier producer on the Rand, but no one seemed to anticipate that they would sink to third position on the list. However, such proved to be the case, the 300 stamps dropped in February at the big Randfontein Central mill doing so well that they not only brought the production higher than that of the East Rand Proprietary mines, but came very near that of the Crown Mines, which made a much better showing than usual; otherwise the Randfontein property would have figured as the largest producer on the Rand, and with only one-half of its big mill at work. The first declaration from the Randfontein property of 55,026 oz. was the result of over six weeks work with the 300 stamps of the new mill, but it not only shows excellent work under the circumstances, but also that both the Crown Mines and the East Rand Proprietary mines cannot, as previously pointed out, hope for the position of premier gold producers of the world when the Randfontein mines and mills all get into full swing. The ultimate output of the Randfontein consolidated property is expected to be in the neighborhood of 100,000 oz. per month, and that of the Crown Mines 90,000 oz., but both these properties have a large amount of work yet to do before they can be expected to approach these figures. Last month the Crown Mines were at the head of the list with an output of 55,717 oz., but the present equipment of the Randfontein property is considered as equal to a monthly production, when in full swing, of 80,000 oz., so that it is possible that ere long there may be an interesting competition for the position of premier gold producer of the world. The following are the six leading gold-producers on the Rand for March:

	Stamps.	Tube-Mills.	Tons Milled.	Output, oz.	Value.
Crown Mines	630	19	130,000	55,717	£236,671
Randfontein	700	19	.....	55,026	233,736
East Rand Proprietary	820	25	164,000	48,261	205,000
Robinson Mine ..	250	6	52,100	27,205	115,560
Geldenhuis Mines.	420	7	71,540	23,406	99,422
Simmer & Jack..	320	6	75,100	23,292	98,938

It may be of some interest to notice that the average daily yield for the whole of the Transvaal in March was £92,637 as against £83,190 in March 1910.

There are indications that while the March gold production was a record one, the profits may not, after all, make a correspondingly good showing, as the increased production comes almost exclusively from the new Randfontein mill where the operating costs are necessarily high. Efforts have been recently made to increase the stamp-duty on the Rand, with considerable success, the new mill at the Roodepoort United Main Reef being at the top of the list with a duty per day of 17.44 tons. This mill, with ¼-in. mesh, has had a duty of over 21 tons per day. The Bantjes comes next, with a stamp-duty of 14.41 tons per day, followed by the City Deep with 13.75 tons, and Simmer Deep with 10.89 tons. Then come seven with daily duties running between 9 and 10 tons, the lowest being the old Camp d'Or mill with a duty of only four tons per day.

Mines of Eastern Oregon

Eastern Oregon is becoming active in mining affairs. In spite of adverse conditions, the legitimate miner has retained his belief in the merits of eastern Oregon mines, and it is largely due to his faith and patient toil that properties idle for years have finally reached a stage of development where all doubt as to merit has been dispelled. Then, the introduction of modern methods of mining and extraction of precious metals has enhanced the value of low-grade orebodies in the district. From 40 to 80% was formerly considered a reasonable saving, and only high-grade ores could be treated profitably. The adoption of scientific methods and the use of modern machinery now make it possible to effect a saving of 95%. Many capitalists are becoming interested in this district, but are making investments only after approved examinations by competent mining engineers. A thoroughly experienced engineer is then placed in charge of the property.

The Highland, situated on Rock creek in Baker county, is developed by adits to an average depth of 300 ft. About 5000 ft. of work has been done and a large reserve of commercial ore has been developed during the last two years. It is a concentrating ore, carrying gold and silver. Considerable shipping ore is found, and $75,000 has been received from this source during the last 18 months. It is planned to drive a 2500-ft. cross-cut whereby 800 ft. of additional stoping ground will be opened. The ore averages $20 per ton. The mine gives employment to 35 men, and Philadelphia investors are among the largest stockholders. Robert R. McCaughey is manager for the Highland Gold Mines Co., John Arthur being consulting engineer.

The Dixie Meadows Mines Co., whose property is 10 miles north of Prairie City, Grant county, employs 70 men. This mine was recently acquired by investors affiliated with L. Vogelstein & Co. of New York. It contains large bodies of silicious and sulphide ore. E. G. Hothorn stated that development alone will be done this year, and only a 10-stamp mill for testing purposes would be erected now. It is said that the future program comprises a 40-stamp mill,

and possibly a smelting plant. J. Nelson Nevius is consulting engineer, and L. A. Greenley is in charge.

The Rainbow mine, in Mormon basin, 16 miles from Durkee, has been bought by the United States S. R. & M. Co., the purchase price being $550,000, of which $200,000 has been paid. The property includes 10 claims and is developed by a vertical shaft and four levels. The orebody is 600 ft. long on the first and second levels, is about 6 ft. wide, and the ore has an average value of $19.50 per ton in gold. The ore is mostly free milling, and the mill is equipped with one 5-stamp battery and seven 2-stamp batteries. The United States company has commenced development, which is to include the sinking of a 1000-ft. vertical shaft, and providing equipment for electric power. A cyanide plant and a new mill of larger capacity will be erected in time. The mine work is in charge of A. P. Anderson, one of the engineers on the staff of the United States company, with Howard S. Lee as local manager.

The Humboldt, situated one mile west of the Rainbow, and on the same lode, is the oldest quartz location in Mormon basin; real mine development on it was begun two years ago. The mine is opened through a 200-ft. double-compartment shaft. The orebodies are continuous for 700 ft., narrowing and widening alternately, showing from 18 in. to 50 ft. of pay ore. It is estimated that 70% of the valuable metals consists of free gold; the remainder is recovered in the concentrate. The property is equipped with a 10-stamp mill and six Johnston concentrators. Short mill-runs have resulted in recovering $50,000, the saving being 90%. Work in the lowest level exposes on the hanging wall from 4 to 12 in. of high-grade ore assaying from $100 to $1500 per ton in gold. The company is preparing to open two more levels and add 10 more stamps to the mill. Equipment for electric power will be put in position at the Humboldt. A force of 30 men is usually employed, C. P. Loomis being superintendent, and John Arthur manager.

Porcupine and Its Future

The control of the Dome Mine, Ltd., at Porcupine is vested in a group, the leaders of which are E. R. Converse, W. E. Corey, J. R. De Lamar, A. Monee, and E. T. Wood, who are closely identified with the International Nickel Co. S. H. P. Pell and Robert M. Thompson are also interested, and W. S. Edwards has an eighth interest in the property. Jack Wilson, who discovered the Dome, was acting at the time for Mr. Edwards, who is a well known manufacturer of gas and electric-light fixtures in Chicago. Mr. Edwards is only one of the large number of Chicago men who have carried on exploration work in Ontario recently. When the value of the Dome mine was appreciated it was easy to interest capital on the basis of an eighth interest clear, with a collateral agreement that the mine should be equipped and a mill built this year. In order to do this, the Merrill Metallurgical Co., of San Francisco, which obtained the contract for the construction of the mill, had special machinery put in by the manufacturer, T. Shriver. The heavy presses were completed within 30 days and were then shipped into Porcupine over the ice on sleds, as it was not then known that the railroad would be completed as promptly as it will be.

At the Hollinger, which has also attracted much attention, the vein is 6 to 8 ft. wide and has been prospected to a depth of 200 ft. Part of the gold is free, and the rest is in the pyrite; a recent mill-test showed a recovery of $80 per ton. The recent rise in the price of the shares was not due to inside manipulation as alleged, but resulted from the cross-cutting of the country-rock, disclosing the fact that both foot and hanging wall are mineralized. The ore is said to be of 'good milling grade' over a zone 100 ft. wide. This probably means that it will go $3 per ton or better. It now can scarcely be doubted that Porcupine will eventually develop into one of the great low-grade districts of the world.

Electrostatic Separation at Cananea

By J. N. Houser

The Calumet & Sonora of Cananea Mining Co., operating a mine and mill 1¾ miles north of the city of Cananea, is building a Huff electrostatic mill to treat the zinc-copper middling produced by the concentrator. There are some 4000 tons of the middling on hand, which assays about 3 oz. Ag, 7% Cu, 30% Zn, 15% Fe, 3.5% Pb, and 7% insoluble, and complete tests on the Huff separators show the following results. Eighty-nine per cent of the copper is recovered in a concentrate assaying 4 oz. Ag, 16% Cu, 8% Zn, 27% Fe, 5% Pb, and 5% insoluble. Eighty-five per cent of the zinc is recovered in a concentrate assaying 54% Zn, 1% Cu, 4% Fe, and 4% insoluble.

The mill now being erected is designed for a capacity of 40 tons per 24 hours. The middling from the concentrator and stock-pile will be brought to the separating plant in 14-cu. ft. mine-cars and raised by a car elevator to the top of the bins. Feed is drawn out of the bins upon a belt-conveyor which delivers to a 3 by 18-ft. revolving dryer, in which a temperature of 750° will be maintained. The dryer discharges into a belt-elevator which raises the feed to a 10-mesh trommel, placed above a set of 20 by 12-in. rolls, which re-grind the oversize. The ore is then elevated to the top of the mill, where it is sized by shaking-screens to the following sizes, on 20 mesh, on 50, and through 50 mesh. The first Huff machines make a rough separation, and then the zinc product and copper-iron products are sent to other machines for the final cleaning.

Mining in Bulgaria

In the district about the capital city, Sofia, a very great number and variety of ores have been found, but until those who hold Government mining concessions show themselves disposed to work their claims in a sensible, practical manner in accordance with modern practice, there will be nothing done except to get out samples by which to sell stock, or perhaps from which to evolve a plan of working. On the other hand, the coal-mining industry is worked quite vigorously; for instance, the Government mine at Pernik, which is showing good results. In 1909 there were 210,993 tons of coal produced at this mine, of which up to the end of the year 198,326 tons was sold (the figures for 1910 are not yet published).

There are also in Trevna four other coal mines of importance; the Prince Boris and the Buduschte, the Lev and the Kalpazar. The coal is of good quality, but because of lack of transportation facilities, little has been produced in the last few years. The opening of the railway from Tirnovo to Borusehititza, by way of Trevno, has given them new life.

The mining laws, passed in 1891, and extended in 1906, have been again altered by the Sobranje. The new features refer principally to the limitation of the privilege to mine and exploit; the manner in which mining concessions may be obtained, and the conditions under which mining rights revert to the public domain; further, concerning the transferring of the rights to third persons, and taxing the mining enterprises, and finally the creation of a Mining Council of the Ministry of Agriculture and Commerce.

Lead and Zinc in Arkansas

Lead and zinc deposits have been known in Arkansas for many years. Lead was noted by Schoolcraft in his travels in 1819 and it has been mined in a desultory way since the settlement of the State. According to the U. S. Geological Survey, the present development dates from about 1899, when there was a great rush to the northern Arkansas field. The ores are galena, sphalerite, and smithsonite. Land for mining is ordinarily leased in 10-acre tracts at 10 per cent royalty. The Arkansas production during 1909 was valued at $57,144, an increase of $2064 over that for 1908.

Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

A GOOD CEMENT for iron in iron is a thick paste of powdered iron, 60 parts; sal ammoniac, 2 parts; and sulphur flowers, 1 part; mix with water and use while fresh.

HARD METAL may be drilled by using carbolic acid instead of another fatty substance as a lubricant, since the latter, by decreasing the friction, diminishes the 'biting' of the drill, whereas the carbolic acid has an etching action.

CORKS may be rendered impervious, and substituted for glass stoppers in bottles of acid, etc., by steeping in vaseline. Acid in no way affects them and chemical fumes do not cause decay, neither do they become fixed by a blow or long disuse.

SPLASH-BOARDS along washing-troughs in change-rooms are a great convenience. They should be built about 14 in. high, should slope steeply toward the trough, and should be water-tight. With them a man can stoop over and throw the water up over his neck, shoulders, and breast, without wetting his clothes.

TO CLEAN metals, especially copper, use a preparation composed of wax, 2.4 parts; oil of turpentine, 9.4 parts; acetic acid, 42 parts; citric acid, 42 parts; white soap, 42 parts. This is claimed to give perfect brilliancy very quickly that persists without soiling either the hand or the articles, and without leaving any odor of copper.

LABELS may be attached to cloth or paper by dissolving gum shellac in 95% alcohol at the rate of 1 lb. shellac to 3 pt. alcohol, and mixing with it any dry color desired. If it becomes too thick, thin with more alcohol. This works free, does not weed out, imparts brilliancy to the color, and wears well.

GLUE for articles of a metallic or mineral character is made by taking boiled linseed oil 20 parts, Flemish glue 20 parts, slacked lime 15 parts, powdered Venice turpentine 5 parts, alum 5 parts, acetic acid 5 parts. Dissolve the glue with the acetic acid, add the alum, then the slacked lime, and finally the turpentine and the boiled linseed oil. Triturate all well until it forms a homogeneous paste and keep in well-stoppered flasks. Use like any other glue.

RUST may be removed from iron or steel apparatus by application of the following solution, first removing any grease by rubbing with a clean dry cloth and then, by means of a brush, using the preparation: 100 parts stannic chloride is dissolved in 1000 parts water; this solution is added to one containing 2 parts tartaric acid dissolved in 1000 parts water, and finally 20 c.c. indigo solution, diluted with 2000 parts water, is added. After allowing the solution to act upon the stain for a few seconds, it is rubbed clean, first with a moist cloth, then with a dry one.

SIDE-DUMPING and bottom-dumping cars are used at many mines to deliver ore to mill-bins. It is usual to run the car into the top of the mill on an open track. There must be at least a walking-board along the side of the track, and often a whole floor is laid, leaving only a narrow space next to the track through which the ore can drop to the bins. An excellent arrangement in such cases is to build up of heavy boards a sloping deflector toward this slit in the floor, so as to force all the ore into the bins. Where this is not done a certain amount of shoveling is commonly necessary.

HARD iron castings may be softened by heating the object to a high temperature, covering it over with fine coal dust or some similar substance, and allowing it to cool gradually. When the articles are of small size, a number of them are packed in a crucible with substances yielding carbon to iron at a glowing heat. The crucible is then tightly closed, and placed in a stove or on an open fire. It is gradually heated and kept at a red heat for several hours, and then allowed to cool slowly. Cast-iron turnings, carbonate of soda, and unrefined sugar are recommended as substances suitable for packing in the crucible with the castings. If unrefined sugar alone is added, the quantity must not be too small. By this process the iron may be rendered extremely soft.

OLD FILES may be rendered useful by the following process: Boil them in a potash bath, brush them with a hard brush, and wipe off. Plunge for half a minute into nitric acid, and pass over a cloth stretched tightly on a flat piece of wood. The resulting effect will be that the acid remains in the grooves, and will take away the steel without attacking the top, which has been wiped dry. The operation may be repeated according to the depth to be obtained. Before using the files thus treated they should be rinsed in water and dried.

POWER COSTS along the Mother Lode are unusually low, and this is one of the secrets of cheap mining. Water-power and electricity are widely available, and where the mining company owns the water the cost may be as little as $1.50 per horse-power month. Where electricity is bought the rates are higher, but still low as compared with those elsewhere. At a particular mine where 40 stamps are operated, the contract price is $4.10 per horse-power month. To get this rate 60% of the rated horse-power of motors fed must be used constantly. Where the use is irregular a flat charge of $1.50 per horse-power month is made for current, to which is added $3.50 per horse-power month figured on meter readings. Under these conditions it is estimated that with fuel-oil delivered at $1.50 per barrel, hoisting and other irregular work may be done cheaper with steam, but that for mills electric current is the cheaper.

WATER-POWER sufficient for part but not all the load is often available for mining and milling. Where electric current is also available it may be used to advantage to supplement the water, though current is generally expensive when it is used to carry only the peak of the load. Aside from this, cutting-in and cutting-out the current requires constant watching. At the Melones mine in Calaveras county, California, W. G. Devereux uses an induction motor which is so connected with the power-shaft that current is taken only when more power is needed than the water-wheel can supply. When, on the other hand, less power is taken than the water-wheel yields, the motor becomes a generator and delivers power to the transmission line. While from the point of view of current generation such an arrangement is not the most efficient, it does have the effect of applying useful power that would otherwise go to waste, and of providing automatic control at the power-station.

TO MARK steel tools, make a rubber stamp with white letters on a black ground. Make up this ink to use with it: Ordinary rosin ½ lb., lard oil one tablespoonful, lampblack two tablespoonfuls, turpentine two tablespoonfuls. Melt the rosin, and stir in the other ingredients in the order given. When the ink is cold it should look like ordinary printers' ink. Spread a little of this ink over the pad, ink the rubber stamp as usual, and press it on the clean steel. Form a thin roll of soft putty, and make a border of putty around the stamped design as close to the lettering as possible, so that no portion of the steel inside the ring of putty is exposed but the lettering. Then pour into the putty ring the etching mixture, composed of 1 oz. nitric acid, 1 oz. muriatic acid, and 12 oz. water. Allow it to rest for only a minute, draw off the acid with a glass or rubber syringe, and soak up the last trace of acid with a moist sponge. Take off the putty, wipe off the design first with potash solution and then with turpentine, and the job is done.

Discussion

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

Secondary Enrichment of Gold Deposits

The Editor:

Sir—Availing myself of your invitation to take part in the discussion department, I wish to say that I have not seen in the columns of your valued journal any reference to the discovery by W. H. Emmons of the agency of manganese in the superficial alteration and secondary enrichment of gold deposits, as explained in the paper read by him before the American Institute of Mining Engineers in November 1910. I am not sure that discovery is the proper word for what Mr. Emmons states, but I do know that his idea is not to be found in any of my mineralogical books, nor in various books on the subject that I have had access to in the Bureau of Mines. An assayer in San Francisco told me that manganese had no solvent effect on gold, and a geologist told me the same. I think that the subject is both interesting and important, and should very much like to hear what some experts have to say of Mr. Emmons' theory. To show how important the subject is, I will quote from Mr. Emmons' paper: "Those deposits in the United States in which a secondary enrichment of gold is believed to have taken place are, almost without exception, manganiferous."

In an article in your issue of May 13 on 'The Bugbear of Gold' many solvents of gold are mentioned, but manganese is not among them. Of course, I understand that manganese is not the direct solvent, but is only the agent that liberates chlorine. If you publish my letter it may stir up some one to give some California ideas on the subject.

H. O. YARROW.

Bowman, California, May 11.

[Our correspondent has overlooked the fact that Mr. Emmons' first published discussion of the rôle of manganese in the secondary enrichment of gold veins was printed in the *Mining and Scientific Press*, December 1, 1909. Mr. Emmons' conclusions seem to us well founded, and the chemistry of the process has been investigated under his direction at the University of Chicago. The result of these experiments was described briefly before the Washington Geological Society by Mr. Emmons in April 1910, and more fully by Mr. Brokaw in the *Journal of Geology*. From the first source we quote as below:

"The experiments were made by A. D. Brokaw. They show that with cold dilute solutions approximating in composition the average of many mine waters, there is markedly great solvent action on gold when manganese is present. The best available data indicate that such solvent action is more than 250 times as great with solutions of manganitic salts as with solutions of cupric or ferric salts of similar concentration. Conversely, it has also been demonstrated experimentally that the precipitation of gold by ferrous sulphate is delayed if manganitic salts are present in the solution. It may be inferred from these experiments (1) that manganiferous gold ores should be more extensively leached of their gold in the upper portions of the lodes than deposits which do not carry manganese, and as a consequence that rich placers would be less likely to be associated with manganiferous than with non-manganiferous gold deposits; (2) that secondary enrichment in gold would extend to greater depths in manganiferous than in non-manganiferous lodes."

The secondary enrichment of gold veins has not attracted the attention it deserves. We published on May 20 a suggestive note on the subject by R. L. Mann, and would be glad to give space to contributions by others.—EDITOR.]

Tunnel-Driving Records

The Editor:

Sir—In your issue of April 8, you make editorial comment as follows:

"Another notable Swiss tunnel was completed on the last day of March, when, after five and one-half years work and the expenditure of twenty million dollars, the Loetschberg tunnel on the route from Milan to Berne was completed for the nine miles of its length. For speed of tunnel-driving the palm goes easily to American engineers, but for ingenious methods of coping with unusual difficulties the Swiss tunnels will long remain famous."

Having had occasion to see work in progress on the Simplon tunnel, I naturally doubted the correctness of your statement that "for speed of tunnel-driving the palm goes easily to American engineers".

Records show that the "palm" so far has gone to the Swiss engineers, and in substantiation of this statement I give the following tables taken from W. L. Saunders' paper entitled 'Driving Headings in Rock Tunnels,' delivered before the New Haven meeting of the American Institute of Mining Engineers in 1909:

AMERICAN TUNNELING RECORDS

The figures represent monthly progress:

	Feet.
Musconetcong, N. J., 1872	144
Nesquehoning, Pa., 1871	165
Hoosac, Mass, 1865-1873	184
Busk, Colo., 1890-1893	202.5
Stampede, Wash., 1886-1888	274
*Cascade, Wash., 1897-1900	301
Aspen, Wyo., 1901	306
Bitter Root Mts., 1908	340
Kellogg, Idaho, 1898	345
Raton, Colo., 1907	412
Sutro, Nev., 1869-1877	417
New Croton Aqueduct, 1887 (in one week)	127
Gunnison, Colo., 1908	449
Elizabeth Lake, Colo., 1908	466

*Another record for this tunnel is: completed tunnel, both ends, Nov. 1899, 527 feet.

EUROPEAN TUNNELING RECORDS

The highest monthly records of European tunneling show not only larger figures, but a better maintenance of approximately the maximum, month after month. In some of the cases here following, several successive monthly records are given:

Mont Cenis, 1857-1870; 297 feet.

St. Gothard, 1872-1881; 436 ft. (with a year's average of 343 ft. This is the only Alpine tunnel driven with top heading.).

Ricken, 1903—; 452, 461, 413, 358 ft. (Hand drilling entirely. Work was stopped on this tunnel nearly a year on account of fire-damp.)

Bosruck, 1902-1905; 546, 526 feet.

Karawanken, 1902-1905; 552, 544, 553 feet.

Arlberg, 1880-1883; east heading, 556, 594, 610, 613, 637 ft. (percussion drills).

Arlberg; west heading, 509, 527, 625, 641 ft. (hydraulic rotary drills).

Albula, 1900-1902; 558, 607 ft. (hydraulic rotary drills).

Tauern, 548 ft., with an average of nearly 525 feet.

Loetschberg; 555, 574, 538, 558, 551, 592 feet.

Simplon, 1900-1905; north heading, 682.2 feet.

Simplon; south heading, 685.5 ft. (This is the world's record.)

Anyone interested in this who has not read Mr. Saunders' paper should find the opportunity of doing so, as it treats the subject very thoroughly. Mr. Saunders has also offered much food for thought to the American engineer in an article entitled 'Shallow Against Deep Holes in Headings' in the April issue of *Compressed Air Magazine*. He gives some of the reasons for the superior results obtained

by the Swiss engineers, and I would respectfully suggest that you give space in your pages to this article.

H. L. TERWILLIGER.

San Francisco, May 10.

[Our correspondent is entirely right in this matter, as an examination of our various accounts of tunnel records will show. The item on which he comments was due to one of those slips that occasionally happen and which was overlooked till too late to correct. It has served an excellent purpose, however, in calling out this interesting comment from Mr. Terwilliger.—EDITOR.]

Surface Indications of Ore-Shoots

The Editor:

Sir—I wish to here thank Mr. F. L. Ransome for his interesting and valuable contribution to the discussion of this subject, published in your issue of May 20. I fully agree with him that conditions involved are complex, and I am not surprised that Mr. Ransome has been able to mention a number of mines where my theory appears not to apply. The sketches offered by him are of interest, as at first glance they all seem to throw doubt upon the correctness of my hypothesis. However, I think that the sketch, Fig. 1, p. 697, assuredly indicates that less stoping has been done beneath the gulches (at the surface) than elsewhere in those mines. In his reference to this property, Mr. Ransome speaks of the probability of the Sullivan ore-shoot pitching northwest under Mild gulch. It may do so, and probably does, but the southeasterly limitations of stoping operations, as shown in the sketch, in the Bunker Hill mine do not suggest that, in the Bunker Hill ground, the ore-shoot is continuous and equally valuable in the direction of the Sullivan shoot. Even if the latter does pitch northwest under Mild gulch, it looks, from an inspection of the sketch, as though there were an interval between the Sullivan and Bunker Hill shoots in which the vein is probably less valuable than the average run of ore of the mine. Fig. 2, illustrating a longitudinal section of the Elkton mine in Cripple Creek district, Colorado, does not show that as much stoping has been done under the depression on the left of the sketch, as has been done under the hill, without doubt there are good reasons for this also, though they are not obvious.

In Fig. 3, showing the workings of the Helena-Frisco mine, in the Coeur d'Alene district, if the dotted lines define the limitations of profitable ore, surely the blanks mostly occur (at the surface) beneath the gulches. The sketch of the Mary McKinney mine, in the Cripple Creek district, appears to contradict my hypothesis. I am not familiar with the mine and evidently was misinformed. The sketch, Fig. 4, does not show the existing condition in sufficient detail to warrant further discussion here. Fig. 5, which shows the workings of the Little Mattie, distinctly seems to disprove my theory, particularly at the Newton and General Thomas shafts, but at the Wisconsin-Corry City mine, as shown in Fig. 6, although stoping has been extensively carried on beneath Cherokee gulch (at depth), the sketch does not indicate that the ore at the surface was sufficiently valuable to warrant stoping. Possibly the problems of mine drainage had something to do with this. A study of the sketch, however, suggests the probability that the ore-shoots in this mine are quite flat, trending to the left, and that there is a poorer zone, several hundred feet in length, between the shoot worked under Cherokee gulch and that on the left under Wisconsin hill, and that this poor zone comes to the surface under Cherokee gulch. The lower stopes in the Wisconsin ground have evidently been opened from long drifts run out from the Corry City shaft, and apparently these drifts were all run from 500 to 800 ft. beyond the stopes adjacent to the shaft without any stoping having been done, which, to say the least, is unusual where the ore through which the drifts pass is worth stoping. Likewise, in the Seven-Thirty workings, as shown in Fig. 7, stopes have been opened from drifts driven east and west from the shaft, while only a little stoping has been done thus far beneath the gulch, except near the surface. This last example seems the most conclusive of all those offered by Mr. Ransome to show that my hypothesis is based upon unsound premises, unless the stopes in the Little Mattie, on the right-hand side of Fig. 5, be excepted. Those on the left in that sketch may be considered as either in favor of or against the theory.

To me it seems that Mr. Ransome, like some others, has misunderstood me. What I endeavored to make clear was, that in my experience shoots of ore rarely crossed gulches or depressions *at the surface*. I make no contention that ore is not to be found or to be expected in depth beneath gulches, but that an ore-shoot in its course along the vein close to the surface, upon reaching a gulch or depression, usually comes to an end, or will be found to have suffered a loss of value even though the vein itself continue otherwise without interruption; for it is not, apparently, absolutely essential that a fault occur to interrupt the continuity of value of the ore. I have attempted no further explanation of the theory, contenting myself with merely stating the facts as I have observed them. I have simply said that (generally) gulches or natural depressions crossing the strike of a lode or vein are the physical expression of disturbance beneath the surface. Mr. Ransome, in his contribution, gives a number of reasons for the occurrence of gulches and depressions. My observation of the occurrences under discussion are by no means confined to the Mother Lode of California, but extend to mines in many States and in foreign lands as well, and when it is thoroughly understood that my hypothesis embraces conditions at the surface or near it only, and not necessarily in depth, I think Mr. Ransome, and perhaps some others, as well, will be willing to admit that the condition I have described is much more common than has generally been supposed. Again, I wish it understood that I do not include in this ore deposits occurring in sedimentary strata—limestone, sandstone, and shale, in the form of sheets, whether as impregnations, or replacement deposits.

In considering this hypothesis, the cause of the gulch or depression should be determined. It is extremely doubtful if any gulch resulting from superimposed erosion, or one formed by a glacier, would come within the category of gulches as here intended. That is, one due wholly to geological disturbance beneath the surface. While it is evident that my theory is not of universal application, the interruption of the continuity of pay-shoots in veins from the causes I have mentioned is of such frequent occurrence as to give the theory much more than passing interest, and, as I have already said, I think that upon investigation my theory will be found to apply with much more frequency than has been generally supposed.

WILLIAM H. STORMS.

Berkeley, California, May 22.

Queensland Gold Yield

The output of gold in Queensland during February was 27,085 oz. fine, of the value of £115,050, being a decrease, when compared with that for the month of February last year, of 7186 oz. in quantity and £30,524 in value. The decrease is attributable to reduced outputs at Charters Towers, where there was a falling off amounting to over 5000 oz.; at Gympie, where the decrease was about 500 oz.; at Mount Morgan, from which a reduction of 1860 oz. is reported; and at Ravenswood, where the falling off was 788 oz. Cloncurry records a return of over 1000 oz., obtained from copper ores, as against nothing for the corresponding month of 1910; the Etheridge shows a small increase; and the Rockhampton fields have an improvement amounting to 466 oz. The output for the first two months of the year was 51,268 oz., of the value of £217,773, or a decrease, as compared with the corresponding period of 1910, of 12,815 oz. and £54,434 respectively. The calls made by gold-mining companies for the month of February amounted to £10,043, and the dividends declared to £6750.

Special Correspondence

KALGOORLIE, WESTERN AUSTRALIA

Drilling Results. — Bullfinch Quiet. — Additions to Geological Survey. — The Chaffinch Flutter. — Annual Meeting of Chamber of Mines.

In my last notes mention was made of the drilling results in the Great Boulder at 2800 ft. The Horse-Shoe people decided to test their own property at this depth, so an arrangement was made with the Boulder company to drill from the Edwards shaft at 2800 ft. Twenty-six feet from the eastern boundary, and 460 ft. from the north boundary, a lode 27 ft. wide, averaging $18 per ton, was cut. This is the old No. 4, or boundary lode, which was in Horse-Shoe ground at 800 ft., and since then has been thrown east and west by faults until it is again their property. This is a loss to the Boulder, but the Horse-Shoe wanted something to liven up shareholders. The latter's main shaft is down only 2100 ft., so it will take nearly a year to reach the lode cut. The Ivanhoe is cross-cutting at 2420 ft., and will sink to 2570 ft. at once. In the Lancefield, the lode has been cut 205 ft. east of the No. 7 level; so far it is 8 ft. wide, worth $10.80 per ton.

The Associated is opening out at 2200 ft., and preparing for the installation of skips. The Bullfinch is quiet, and people take little notice of reported rich finds in the district. In the parent mine the ore appears to be lower in value than usual. The treatment of rich ore is to be discontinued after the present month. The hoisting machinery is erected, and sinking will be resumed. Shares have dropped a great deal, and now stand at $5, about par, as compared with $15 some three months ago.

The Western Australian Government has lately made several additions to the staff of the Geological Survey, and most of the new members are to study the Yilgarn field. Of course, in this country, work can proceed all the year round. Much attention is being directed to the Ora Banda field, but rain is badly wanted. The Associated Northern and Oroya Exploration are working their options. The Chaffinch mine, which was the cause of the Bullfinch boom smash, has been prominently before the public again over the conspiracy case, in which three well known Eastern mining men were prosecuted by the Government, for defrauding the public. As predicted by many, they were released. Some peculiar methods of speculation were brought to light; and those who gave evidence for the Crown were worse than those prosecuted. It was simply a case of bulling and bearing scrip by men who knew the game; but without doubt it was a disgraceful affair. As a reminder of the boom last year, two town blocks at Bullfinch which were sold for $2500, when put up for auction recently failed to get any bids at all.

The annual meeting of the Chamber of Mines was held last month, and R. Hamilton, the president, discussed the more important points in connection with mining. During the past year 2,884,298 tons (long) was treated in Western Australia for gold, valued at $30,200,000; a shrinkage of $3,270,000. The East Coolgardie (Kalgoorlie) and East Murchison fields were responsible for 78% of the decrease. The chief developments in the outside mines were reviewed, not forgetting the recent drilling results at Kalgoorlie. The labor troubles, and the awards of the Arbitration Court were commented upon; also, the Government action in procuring reports on explosives in mines, and miners' phthisis; and legislation and its effect on mining generally.

For over a year, the Chamber of Mines has been preparing for publication 'West Australian Mining Practice', as written by Mr. Cleland, now manager of the Perseverance. The work is now published, and is a valuable book of reference for mining methods in this State, especially in Kalgoorlie. The book is well supplied with maps, plans, and pictures. Some five years ago, the metallurgical practice on our principal mines was written for the Chamber by R. Allen. Now we have a second and revised edition of the work by Gerard Williams. This is being prepared for publication at an early date. This pair of books should be of interest and value to American engineers. In the February issue of the Chamber of Mines Report is a full description, with detailed drawings of the vacuum treatment of slime as practised at the Oroya Exploration and Lake View Consols re-treatment plants, T. B. Stevens and W. R. Degenhardt being leading exponents of this treatment here.

JOHANNESBURG, TRANSVAAL

Changes in the Miners' Phthisis Bill. — Equitable Arrangement. — Basis of Fund. — Amount Paid. — Native Labor Statistics.

The Minister of Mines in the Union Parliament has proposed changes in the miners' phthisis bill that completely alter its character. When first introduced it was proposed to divide its burden for the first two years only between the mine-owners and the Government, but the most crucial amendment now proposed is to compel the miners to pay one-fourth of the amount contributed by the owners, while the Government has to pay one-half of the sum awarded to the miner as compensation. It will be recollected that at the time of the introduction of the bill it was pointed out with considerable force on the part of the mine-owners that the burden of such a proposal would be severely felt by the mining industry, which already pays, in one shape or another, the bulk of the taxes, and the warning thus given seems to have had effect, for the whole bill has been reconstructed and brought more into harmony with the wishes of the mine-owners. Naturally the Labor Party in the House has condemned the proposal to make the miners contribute, the result of which will allow the amendments to be fully considered. It is generally admitted that miners' phthisis can be avoided if proper steps are taken to prevent it, and one cause of it is the neglect of the miner who refuses to take even the steps provided for his protection by the mining regulations. Under these circumstances it seems only fair that the miner should contribute. It is generally admitted that good ventilation is essential for the prevention of phthisis in addition to the watering arrangements. Until lately artificial ventilation was practically unknown to the Rand, although at the present it is being extensively adopted. The lax manner in which the Government enforces the mining regulations with regard to ventilation and the prevention of dust is sufficient to make it also liable, and the new proposals by which it is provided that the Government, mine-owners, and miners should all pay the damages caused by their joint neglect cannot be otherwise than considered just. Then, again, the establishment of a fund to which all parties will contribute, and the placing of its administration solely under the control of a board, instead of leaving the miners to sue the mine-owners for compensation, must be considered a distinct improvement upon the former proposal, whereby the bulk of the benefits would probably be spent on law costs. The basis of the fund will be a monthly contribution from the mine-owners of £1 for each rock-driller, and 10s. for each and every other white employee underground, of which one-fourth will be deducted from the pay of the miner. The Government will pay one-half the sum awarded as compensation, while the Minister of Mines reserves the power to call upon the miner to increase his contribution if necessary. A maximum amount of compensation of £250 for phthisis and £500 for both phthisis and tuberculosis combined is proposed, but not only the amount, but likewise the method of payment, whether in the shape of a lump sum or pension, is proposed to be left to the discretion of the board. The Minister of Mines will draw up a list of the mines in which the dust is considered liable to cause miners' phthisis, and on publication in the *Gazette*, will become liable for the payments provided. Natives are provided for by making miners' phthisis the same as a personal injury under the Native Laborers' Regulation Act.

The Chamber of Mines' returns for the month of March also contained the welcome announcement that the number of native unskilled laborers for the mines was still increasing. In March the gain was 3250, and constituted another record, as the total number employed in mining during March was 312,011, as against the previous record of 1910 amounting to 206,680. The gold mines employed 193,457, another record number, the number employed during the corresponding month of last year being 178,345. Despite this increase in the number of natives coming to work in the mines, the demand is far from being satisfied, and it is doubtful whether the mines will ever be able to obtain all the unskilled native labor they require.

LONDON

APPOINTMENT OF COAL MINE INSPECTORS.—TERMS OF APPOINTMENT.—RULING AS TO WHAT IS A MINERAL.

For some years coal miners in Great Britain have been asking for the appointment of inspectors drawn from their own ranks. There were two reasons for this demand. In the first place, the present Government Inspectors of Mines are high officials, and as such are suspected of being invariably in sympathy with the employers and owners; and, second, these high officials are not sufficiently in touch with the mechanical details of operation, which appear small to them but which may be of immense importance from the point of view of the safety of the worker. More often than not, a serious accident is caused by some apparently trivial matter. The Home Secretary has now decided to appoint thirty sub-inspectors drawn from men who have had five years continuous underground experience; two will be allotted to each of the six mining districts, with an extra one for Yorkshire, and two will devote their attention to quarries. Circulars have been issued inviting applications. The applicants will first have their general qualifications investigated by a committee of the Home Office, and those selected will be subjected to competitive examination, one examination being held in each district, thus ensuring that the men shall have thorough knowledge of local conditions. Candidates are expressly warned that political or social influence must not be invoked; to present an endorsement from a Member of Parliament would be fatal. The subjects covered in the examination will be such as will prove the candidate's knowledge of ordinary routine practice, and his ability to write an intelligible report. The salary is to be £150 per year, increasing £5 yearly to £200. The scheme has not been sufficiently elaborated for it to be possible for the Home Office to give an exact outline of the duties of these new inspectors. The mine-owners and their friends are inclined to be sarcastically sceptical as to the value of the services of these working-men inspectors, and they call the creation of this new class of official a sop to the Labor party. They allege that a competent pit-man will not find the post attractive, for he can earn as much in four days, and the absence of any limit to his hours of labor and responsibility will form an unpleasant feature of the work.

During the last three years I have recorded several lawsuits undertaken to determine what is a mineral according to the meaning of the Railway Consolidation Act of 1845. The Act said that the railways only had surface rights, and did not own the 'minerals' below. These lawsuits are necessary to determine the status of each mineral, and they all eventually go to the highest court, the House of Lords. Generally speaking, a 'mineral' is held to be any constituent of the earth's crust that has a special value. China-clay has been adjudged to come within this category, but, on the other hand, stone suitable for building purposes has not. The most recent case relates to fire-clay, and the House of Lords has decided that this substance is undoubtedly a mineral within the meaning of the Act. The Caledonian Railway is owner of surface lands, and the Glenboig Union Fire Clay Co. works the seams of fire-clay underneath. It was held that fire-clay was of notable value and was the basis of a special industry, therefore the Railway Company's claim was quite untenable.

JARBIDGE, NEVADA

WORK ON THE CLARK-FLETCHER LEASE.—THE TRUE FISSURE G. M. CO.—PROGRESS ON THE PAVLAK.—NEW VEIN ON THE RELIANCE.—A DISCOVERY ON THE WEST SIDE.—TELEPHONE AND A BANK.

The season is backward this year, and this has had a tendency to retard prospecting, but where work is going on the results are very satisfactory. On the Clark-Fletcher lease on the North Star ground two shifts have been working all winter. The vein is opened on two levels to a depth of 150 ft. and is 8 to 12 ft. wide. The value of the ore is estimated at $17 per ton, corresponding to $300,000 of ore blocked out. There are many places where the vein is rich. A 60-ton mill is now on the way to the mine and will be erected as rapidly as possible.

The True Fissure Gold Mining Co. also has good ore in its mine on Jumbo peak, and is now building a road to the millsite at the foot of the falls on Fall creek. This is an ideal site for a mill, with good water-power near; it is two miles from the mine. The mine is on the main Crater vein, and the surface of its Third Peak claim makes a good showing. The development work this winter has shown the regularity of the vein, and has opened up a large orebody. The adit is now in 180 ft. and shows good ore all the way. The width of the vein at the month of the adit is 2 ft., and at the face it is 4½ ft. wide. The value of the ore has also shown a steady increase from $12 at

SCENE IN JARBIDGE DISTRICT, NEVADA.

the mouth of the adit to $60 per ton at the face. The depth at the face is about 90 ft., which gives a good back of ore to stope from.

The Pavlak mill is making good progress, but as it is a large one it is probable that both of the preceding mills will be in operation before this is finished. The cross-cut from the first drift to the north from the adit is in a large body of quartz. The conditions along the Pavlak vein can be said to be very promising. Theodore Parks has purchased an interest in the lease on the North Star vein with George A. Fisher and has found a good body of high-grade milling ore. This ore is changing somewhat and now resembles that in the Bourne vein, where Clark and Fletcher have a large orebody.

On the opposite side of Bourne gulch Lige Fletcher is opening another vein on the Reliance claim of the North Star Co. R. S. Silver is associated with him in this new lease, which is on a parallel vein about 300 ft. east of the North Star vein. They have traced the vein for a distance of several hundred feet. In one place where they propose to start development work, they have stripped the vein, which is 8 to 12 ft. wide. Another new find made at some distance from any previous one tends to prove the extent of the mineralized area. This was made by A. E. Bettles, near the head of Bear creek on the Mohawk claims, and, from the little work so far done it promises to be a very

important find. Samples from along the vein give assays of $4 to $16 per ton and an average sample of 5 ft. of the vein from one of their prospect holes gave returns of $7.20 per ton. This property is over three miles southwest of the town and on the west side of the Jarbidge river. This will greatly stimulate activity on the west side and along the Bear creek section. The Jarbidge Nevada Co. is already at work near the mouth of Bear creek, the Ham-And Co. is opening a vein on Bear creek ridge one-half mile south of Jarbidge, Nevada; some good float has been found on the Overalls group, another mile south, and now the Mohawk find, still farther south, and all on the west side, is promising for this portion of the camp.

The Mohawk claims are just west of the Yosemite claims, and join on the south the Big Four group, which belongs to the Buhl Jarbidge Co. The new wagon-road from Deeth crosses this ground just before reaching the Bear creek summit. The claims are well covered with timber, but are near the head of the water supply. Forty men are at work on the new road from Deeth; it is being built with a 12-ft. road-bed. The poles are being set for the telephone line into Jarbidge and it will be finished as soon as possible. As soon as the line is open a bank will be established in Jarbidge.

FAIRBANKS, ALASKA

Reports of Activity in Quartz Development on Tanana Tributaries.—Two Dredges to Be Operated.

The miners of Cleary creek are excited over recent work in the cross-cut being driven on Wolf creek by A. W. Balzimer, in which high-grade gold ore was found at 350 ft. from the portal. Balzimer and partners are driving both ways on the vein from where it was intersected by the cross-cut. After cross-cutting 120 ft., Utigard and Nerhland, of Chatham creek, have opened the lode for which they were driving. It is 4 ft. wide and contains good ore. Sinking continues on the Golden-Sherrard lease at the head of Cleary creek. After sinking through barren rock, ore was found in a 5-ft. vein at 112 ft., which is believed to run about $100 per ton. A boiler and hoist will be provided. Stoping is being carried on at the Tolovana Mining Co.'s property on Willow creek. A mill will be built on the claim this summer. Work will be commenced on the lower shaft of the Friedrich lode. The shaft will first be timbered, a 30-hp. plant set up, a tramway built to Vault creek, and a mill erected. Sinking will commence as soon as the plant is ready. The timber for the mill on the Rhoads-Hall claims has been shipped from town. It is intended to have the building ready by the time the stamps arrive from San Francisco on the first boat. August Hess is driving on the 80-ft. level from his Fairbanks creek 120-ft. shaft, which will be put in readiness for further development. A hoisting plant will be put in and a small mill may be built this summer. There is enough ore exposed to warrant the expenditure.

Hoel Bros., Johnson, and Witmer, who recently sold their Vault creek holdings, have a 20-hp. plant at the head of Treasure creek, where they have some quartz prospects. Learning by previous experience that windlass work has narrow limits, they are going to start right. Before proceeding with further development work, L. M. Drury and associates will sample the properties bought from Hoel Bros. & Co. Hirshberger and Zimmerman are working on their Skoogy gulch lode with gratifying results. Good ore has been found in the bottom of the 50-ft. shaft, and driving is in progress at that depth to determine the width of the shoot and to better ventilate the mine. The vein varies from 4 to 5 ft. thick, the pay-shoot showing from 1 to 2 ft. quartz. The walls are well defined, and the quartz, being free from the other vein matter, can be stripped with little loss. A bonding and leasing company is being formed by F. S. Gordon among local capitalists. The capital stock is put at $200,000, and if $10,000 is pledged, W. B. Vanderlip, of London, will be placed in charge to pass upon leases and to develop them to the point where big capital can be interested. The $10,000 was practically all subscribed in two days.

Two dredges will be operated in the camp this summer by the dredging company reorganized by G. G. Lemons and W. W. Powell, the English company organized by the former having taken up the options on Fairbanks, Twin, and Pedro creeks. The attorney for the company states that there is nothing to hinder the consummation of the deal, as the company is composed of some of the richest men in England.

SILVERTON, COLORADO

The Silver Lake Lease.—Production at the Iowa Tiger.—W. B. Lowe Failure.—New Equipment for the Silver Lake.—Proposed Consolidation.—Litigation Over the Old Hundred.—New Liability Law.

The San Juan district is experiencing a late spring this year and new operations are delayed nearly a month. Much of the work planned has now been started, and arrangements have been completed for the rest to start as soon as the roads are clear of snow. The most important development of the month is the consummation of negotiations for the Silver Lake lease, which has now been signed. The lessees are Messrs. Goudy, Maris, Barry, and Fox, all experienced operators in this district. Work started on May 20 with the repair of the power and tram lines, and underground operations will be pushed as soon as supplies can be taken to the mine. Under the lease the Garfield Smelting Co. operates the tram and mill, and the lessees the mine. The minimum amount agreed upon is 50 tons daily, and the lessees expect to be producing 100 tons daily within 90 days. Should this property meet expectations and be restored to the list of active shippers, it will add more than any other item to the feeling of confidence that is gradually returning to this old district. The Gold King is working steadily, and the mill is treating 250 tons of crude ore per day, resulting in a production of 55 tons of concentrate. The company at present employs 100 men. The Iowa Tiger Leasing Co. has opened up several new ore-bodies during the past month, and the concentrate shows high value. Two cars sent out last week assayed: Au, 1.7 oz.; Ag, 11 oz.; Pb, 37%; Cu, 2%. The mill is treating 100 tons per day and for the past month shipments of concentrate totaled 400 tons. The Iowa Gold Mining & Milling Co., owner of the Iowa and Tiger mines, paid a dividend of ½% on May 15, or a total of $8333. For the two years operation under lessees, royalty payments have amounted to $60,000. The mine is in excellent condition and should continue production for some time to come. The ore contract with the Ohio & Colorado Smelting Co. has been renewed at a slightly better figure than the previous contract. The District Court is now in session, and the affairs of the Kittimac, Peerless San Juan, and W. B. Lowe companies are being adjusted. The W. B. Lowe company is not represented by counsel, and the creditors, whose claims total $40,000, have agreed on a division of the company's property, which consists of the Arpad mine, the Contention mill, and a bond and lease on the Yukon mine. The company spent nearly $200,000 in developing these mines, and the failure seems entirely due to reckless and extravagant management. The Sunnyside, at Eureka, continues its steady production, and no changes of note have taken place. The Silver Ledge is driving a raise from the sixth level to the fifth, and the opening exposes excellent ore. The raise produced about 100 lb. of high-grade gray-copper ore, but no more has been discovered. Five cars of new machinery for the mill are in the Silverton yards, and will be taken to the property when the railroad has been cleared of snow. The mill will be started sometime in June and will handle 200 tons per day. The mine produces a lead-zinc ore with a talc gangue, the percentages of lead and zinc being about equal. The mill at present has crushers, rolls, Chilean mills, Richards classifier, Callow tanks, and Wilfley tables. To these will be added one set of rolls, trommels, jigs, classifiers, and a set of Callow

tanks. This addition is expected to raise the capacity and percentage of saving, which at present varies between 67 and 72%. The Hercules is being sampled, and future operations will depend upon the results obtained. Should operations be resumed, Tom Kane, former manager of this property, will again assume the active management. The Highland Mary mine is for sale and an attempt is being made to consolidate it with the Shenandoah and Trilby properties. Among the smaller properties that are operating and that will make some shipments during the summer are the Columbus, Gold Bug, Esmeralda, Kansas City, Emma, Shenandoah, Pride of the West, and Kankakee. The Old Hundred mine is involved in litigation, and the owner is attempting to wrest control from the lessee. Local merchants and laborers have large claims against the lessee and affairs are in a very tangled state. The Colorado legislature, during its recent session, passed a law known as the lien liability law, which holds the owner of a mining property liable for debts incurred by lessees. This bill was proposed by Senator Joyce and Representative Slattery of this district and has already caused wide discussion. It will be far-reaching in its effects, and practically compels mining companies to require ample bonds of lessees to protect the companies against debts. It is generally believed by mining men of this district that it will prove beneficial, as it may put an end to 'wild-cat' operations under cover of bonds and leases. This form of operation has been one of the greatest curses of the San Juan, and it is hoped that properties will now be conducted by responsible operators and not by irresponsible, incompetent, and extravagant lessees, with resulting failure, leaving large debts to burden the community.

NEW YORK

REORGANIZATION OF UNITED COPPER.—BUTTE-BALLAKLAVA.—SALE OF CORDOVA COPPER CO.—CLOSING DOWN OF MONTGOMERY-SHOSHONE.—GROWING INTEREST IN PORCUPINE.—REA CONSOLIDATED.—MINING EXCITEMENT AT TORONTO.

It is understood that there is to be a reorganization of the United Copper Co. The public and the shareholders alike have never been able to secure any kind of a statement from the Heinze management regarding the company's operations or assets. There is some talk of a call upon the shareholders for $1 per share, but as the stock is issued fully paid, it will be necessary to organize a new company to do this. The annual meeting will be held the first week in June, but it is not expected that any light will be shed upon United Copper's operations during the past year. To protect itself against any flank movements, the Butte-Ballaklava management has organized an iron-clad pool, and the majority of its 250,000 shares of stock has been deposited in a bank at Duluth. The statement is made that outside interests have been endeavoring to gain control of the company, using the suits brought against the company as ammunition in their campaign. The Butte-Ballaklava has built something of a back-fire by instituting a suit against the Anaconda to recover $1,376,095, being the estimated value of ore wrongfully extracted from the Butte-Ballaklava ground. The Inspiration Copper Co. has acquired full title to the holdings of the Cordova Copper Co., which adjoin the Inspiration at Miami, Arizona. The price reported to have been paid for the minority interests is $76,000.

It is expected that the curtain will be lowered for the last time on the operations of the Montgomery-Shoshone when the annual meeting is held in the latter part of the current week. It is practically decided to close down the property and dismantle the big plant that was once looked upon as one of the principal producers in Nevada. The company will realize something from the sale of its mill, but will close its existence heavily in debt to Mr. Schwab. The Granby mines in British Columbia have been forced to shut down by reason of the strike of the coal miners. Some 500 men are thrown out of employment at the Granby property, and the smelter at Grand Forks will be closed down in a day or two. It is said that no work will be begun until the coal strike is out of the way.

Though there has been some temporary increase in interest in copper shares and in the announcement that in spite of prevailing conditions Utah Copper is to increase its output after August 1, when the much talked of curtailment agreement will expire by limitation, still the chief centre of interest in New York is in the Canadian goldfields. The endorsement given by well known mining engineers is beginning to have weight with the public, and the belief is growing that Porcupine will develop several large mines. There is a decided trend of opinion to the theory that good ore will be found to exist at depth. It is this question that has so far been the stumbling block in the way of progress. The fire which occurred recently has had no effect on prices, or on activity. The greatest loss was sustained by Timmins Brothers, the 30-stamp mill which had been erected and equipped for the Hollinger having been destroyed. Orders have already been placed by wire to duplicate this equipment, consisting of the mill and a cyanide plant, the latter having been just completed when the fire occurred.

GRANBY SMELTER, GRANBY FORKS, B. C.

A large part of the interest in Porcupine during the past week or ten days has been centring in the Rea Consolidated, in which the Consolidated Gold Fields of South Africa had at one time a large interest, but for some reason saw fit to sell out. The property is now controlled by the same interests that control the Golden Cycle of Cripple Creek; John T. Milliken of St. Louis, Frank G. Logan, of Logan & Bryan, and their friends. Work at 200 to 250 ft. depth in the Rea is said to have shown such good ore as to make the property one of the sure mines of the camp.

Toronto has become the centre of mining deals, real and imaginary, and there is an army of promoters and boomers fanning the flame of excitement in the hope of inducing the public to let its enthusiasm run away with its judgment, so that paper promotions may look like real mine development. The way of this class of gentry is, however, getting harder to travel all the time. E. N. Foss, governor of Massachusetts, has signed the bill making it a crime, punishable by a fine of $5000 or ten years imprisonment, or both, to make or cause to be made public any false statements regarding the merits of the stock in any corporation, or of the financial condition of any corporation.

Some important bills passed by the legislature of Colorado also treat upon the mining industry. The most important of these is the bill providing that mines shall be taxed upon their net returns, not upon the gross production. The question of how to assess non-producing properties is a difficult one; it was finally decided to materially reduce the present local rates. How to assess mine improvements is also a puzzle, the only equitable arrangement is some simple and easily applied rule that can be made uniform in its imposition. The Colorado legislature also made smelting and sampling companies public-utility corporations. How this will work out in practice is yet to be seen.

General Mining News

ALASKA

Juneau District

The report of the Alaska United Gold M. Co. for the month ended April 15, 1911, is as follows: Ready Bullion 120-stamp mill: Ore crushed, 17,799 tons; concentrate saved, 420 tons; estimated gross value of free gold recovered, $21,212; value of concentrate, $16,714. Total realizable value, $37,548; operating expenses, $30,508; net operating profit, $7039. Construction expense, $1260; yield of ore, $2.13 per ton. The 700-Ft. Claim 100-stamp mill: Ore crushed, 17,595 tons; concentrate saved, 413 tons; gross value of free gold, $18,887; concentrate, $15,687. Total realizable value, $34,256; operating expenses, $28,002; net operating profit, $6254; construction, $5803. Yield of ore milled, $1.96 per ton. Development on Ready Bullion claim, 359 ft.; on 700-Ft. Claim, 494 ft. Stock of ore broken, 721 tons in former, and 52 tons in latter.

Prince William Sound

The Valdez M. Co. has driven 120 ft. along the course of its lode, and from this adit cross-cuts 20 ft. apart have been driven through the vein, demonstrating that it has a width varying from 7 to 11 ft. It is claimed the ore assays about $100 per ton. The face of the adit is 130 ft. below the cropping. The intention is to extend the adit, and drive another level, starting it 400 ft. lower on the mountain side. Interest in the Cliff mine has been increased by the recent discovery of a body of ore, not previously opened, which proves to be on the main vein. A clean-up at the Cliff on May 9 amounted to $8500. The Blue Ribbon Gold M. Co. has given a 5-years lease of its six claims on Mineral creek to Daniel Johannson and G. E. Erickson, of Nevada, the lessees to pay a royalty of 20% of proceeds after the pay-roll has been met. The lessees also have an option to purchase the mine at $200,000 if taken within a year, but at a higher price if the option is exercised within any one of the subsequent years of the lease.

It is announced at Cordova that the Copper River & Northwestern Railway Co. is to have a survey made this season for an extension of its line from mile 191 a distance of 60 miles northeasterly into the White River region, this route being through a mineral region. The Alaska Road Commission announces that $20,000 will be spent this year in so improving the trail between Chitina and Willow creek as to make it passable for wagons and automobiles.

Seward Peninsula

The Wild Goose Mining & Trading Co. is to operate its dredge on upper Ophir creek, near Council, this season, the work to be in charge of Gilbert Russell. The dredge was built last year and was operated satisfactorily for 10 days in October. It has a close-connected line of 58 buckets, each of 3½-cu. ft. capacity, the power for operating being supplied by a 125-hp. gasoline engine. The rated capacity of the dredge is 2000 cu. yd. per day.

ARIZONA

Mohave County

The C. O. D. mine and mill are being made ready to operate again. The intention is to mill the ore on the dump and that which is exposed in the stopes. The property is 15 miles out from Kingman, near Mineral Park.

Pima County

The Plumed Knight claims, 18 miles south of Tucson, have been purchased of L. D. Chillson by the Pioneer Smelting Co., the second payment having been made recently according to the terms of a lease and bond signed last January. This is but one of several properties which this company is acquiring. A smelting plant is to be built eventually. Development on the Golden Age group of claims, 64 miles southwest of Tucson, has resulted in exposing a vein of ore containing wulfenite, or molybdate of lead. Development on other similiar deposits leads to the belief that gold ore underlies the wulfenite. The Golden Age operators have on the ground the equipment for a mill in which surface ores are to be treated.

Pinal County

The two units of the Ray Con. mill, which are in operation, are turning out a concentrate containing 71% of the assay value of the ore treated. This percentage of saving is said to be reached even when the mill is being run at the maximum capacity of 2400 tons per day for the two units. While the smelter of the Ray Con. is being constructed the concentrate is being shipped to the El Paso smelter. The Ray mill and smelter are both at Hayden. David Cole, formerly with the Cananea Consolidated, is now manager for the Ray company, with George O. Bradley as superintendent of construction.

CALIFORNIA

Amador County

The operating profits of the Central Eureka mine for April amounted to $5000. The Fremont Con. M. Co., the property of which is between Drytown and Amador City, pays a monthly dividend of 2c. per share, amounting to $4000. Arthur W. Goodall and Wales Palmer are manager and mine superintendent, respectively. R. S. Rainsford, in charge of the Argonaut mine, close to Jackson, has purchased new hoisting machinery, which will be put in position this month. It is stated that the vein, where opened at the 3400-ft. level, is 20 ft. wide, containing ore of good grade.

Butte County

The Natomas Consolidated is operating two dredges in Oroville district, and has a third dredge under construction for work in the same locality. The new one will have 15-cu. ft. buckets.

Inyo County

(Special Correspondence.)—The report of the Skidoo Mines Co., for April, showed that 1026 tons of ore was milled, from which there was recovered $14,254 by amalgamation, and $3282 by cyanide treatment. The costs of operating were $7734; development expense, $1068. Net profits for the month, $8734.

Skidoo, May 25.

The Randsburg *Miner* notes the sale of the Arondo mine, situated in Argus mountains, in the southwestern part of Inyo county, to A. B. Rogers and associates of Los Angeles, the purchasers now being in possession of the property, with Charles E. Anderson in charge of the work. The equipment includes a small mill for cyanide treatment.

Nevada County

The 20-stamp mill at the Pittsburg mine at Nevada City is running on ore taken from the stopes between the 1000 and 1100-ft. levels. The deepest workings in ore consist of drifts on the vein at the 1300-ft. level. The vein was opened at this depth by driving a 40-ft. cross-cut from the 1300-ft. station. Raises are to be driven on the vein from the 1300 to the 1100-ft. level. The stoping ground between those levels is expected to supply a big tonnage of ore. Mark B. Kerr, managing director, is in charge of the work. The Fairview mine is now under the management of Arthur W. Hoge, who is identified with the Montana mine, at Grass Valley, and the Downey at Jones bar.

Sacramento County

The Natomas Consolidated of California is operating its Natoma dredge No. 8 on American river, in the vicinity of Folsom. It is handling about 500 cu. yd. of material per hour, digging in most difficult ground, consisting of cemented gravel and heavy clay; the digging extends considerably into the false bedrock of volcanic ash. Dredge No. 9, now nearly completed, is to be started in operation this month on Rebel hill, one mile from dredge No. 8. Both dredges have 15-cu. ft. buckets, and dig to a depth of 55 ft. below water-line. This company has placed with the Yuba Construction Co., of Marysville, an order for the building of Natoma dredge No. 10, which is to have a steel

hull, 150 by 50 ft., and 10 ft. in depth. It is to be equipped with a chain of 15-cu. ft. buckets, and will be operated on Humbug hill, near Folsom. The cost of this dredge will be close to $275,000. It is the first one with a steel hull to be built for work in California. The Yuba Construction Co., which designed and built all the dredges mentioned, constructed two steel-hull boats for the Yukon Gold Co., for its work at Dawson.

San Bernardino County

The Bob Young and other mining properties, situated 14 miles from Barnwell, have been sold to a company of Philadelphia people at $150,000, of which $75,000 is said to have been paid in cash. It is claimed the Bob Young has 7000 ft. of development work.

Shasta County

(Special Correspondence.)—The Western Dredging Co. has arranged to operate a dredge this season on the Sacramento river 2½ miles above Redding. The dredge is of the Dubois suction type. The Mammoth Copper Co, is operating three furnaces, and recent improvements in collecting fumes are expected to make it possible to continue through the summer. The difficulty in trying to cool the smoke sufficiently to avoid injury to the woolen bags during the passage of the smoke has been apparently overcome. The company has a force of about 100 men at work in the Quartz Hill mine, Old Diggings district, where silicious gold ore has been opened. The Noble Electric Steel Co. is arranging for three new furnaces. Within three months the company expects to be producing pig iron on a large scale. In the meantime operations continue at the iron mines in the Pit river canyon, while the chrome deposits are also receiving attention. The electric smelter is built at Heroult on the Sacramento Valley & Eastern railway, a short distance from Redding. The officials of the Balaklala Copper Co. have been cited to appear before Judge Van Fleet, June 19, in the U. S. District Court at San Francisco, to answer to the charge of the Farmers' Protective Association that the decree of the court relative to the smelter fumes is not being obeyed by the company. It is understood that the company will maintain that the smoke from its Coram plant is not causing any damage to crops and that the decree of the court has been complied with.

Redding, May 28.

Sierra County

(Special Correspondence.)—There is some mining activity in the vicinity of Sierra City. It is reported that a vein has been opened in the Sacred Mound mine. The ore recently discovered is said to be richer than any previously found. Operations are also in progress in the Bullion or Colombo mines, as well as in the Swastika. The old Sierra Buttes mine, formerly operated by the Sierra Buttes Mining Co. of London, which also owned the Plumas Eureka mines at Johnsville, Plumas county, has ten additional stamps in operation on a good grade of ore. In addition to these, the Keystone and San Luis are operating on a small scale. This season promises to be favorable, the unusual fall of snow in the Sierras guaranteeing an adequate water supply for the next six months.

Sierra City, May 27.

The Rio Antigua M. Co. of Los Angeles has obtained a renewal of the bond under which it has performed a great deal of work on the South fork placer property in the vicinity of Forest. It is said that $50,000 has been expended by this company on the property. Work is to be resumed this month. The Standard mine, in Sailor ravine, owned by R. E. Blevins and Jason Frye, is to be equipped with a 5-stamp mill. They have ore on the dump and in the stopes sufficient to keep 5 stamps crushing for some time.

Trinity County

The Payne ranch, in the vicinity of Trinity Center, considered good dredging ground, has been sold by G. W. Payne and others to a company formed at San Francisco, in which Payne is included. W. L. Christy, one of the eight stockholders, is said to have prospected the ground two years ago. A dredge, having 7-cu. ft. buckets, that formerly was operated in Siskiyou county, is to be moved to the Payne property.

COLORADO

Thirty-six members of the senior class of the Colorado School of Mines, Golden, accompanied by six of the professors of that institution, visited and inspected mines, mills, smelters, and power plants in Colorado, Utah, and Montana last month, and did some underground and field geological work. They made a study of the New Monarch, Wolftone, and Silver Cord mines, and the Yak tunnel, at Leadville; the Daly-Judge and Daly West at Park City; the mines of the Utah Copper Co. and Utah Consolidated in Bingham district; the St. Lawrence, High Ore, Diamond, Belmont, Anaconda, Never Sweat, and Butte & Superior mines at Butte.

Clear Creek County

The Conqueror mine, situated at Empire, is to be reopened and operated this season under direction of George Schneider. The small concentrating mill is to be put in operation. The 5-ft. vein tapped by an adit in the Josephine, 1400 ft. from the portal, is said to contain ore assaying 65% lead and 35 oz. silver per ton. The Argentine Central railroad, extending from Georgetown up toward the pass, is probably open for traffic by now, and ore shipments from the Santiago mine to the Golden smelter doubtless have commenced.

Fremont County

(Special Correspondence.)—The new tailing mill, built at the Union plant of the United States Reduction & Refining Co., at Florence, was finished and put in operation in April. It was built to treat the stuff in the tailing dump from the main plant, this material being pulverized by tube-mills in which cyanide solution is used. Following this the pulp is passed over blankets, thence to large tanks containing Dorr thickeners. Merrill presses are used in precipitating with zinc dust. This mill was built under direction of J. Q. MacDonald, manager of the Union plant.

Florence, May 27.

Hinsdale County

The Lake City *Times* publishes an account of the starting of the Rankin plant, and states that the first ore treated contained silver, 4% sulphur, 10% lead, 5% zinc, 1% copper, and about 80% silica, the cost of treatment having been 75c. per ton. It is claimed the extraction reaches over 90 per cent.

Lake County (Leadville)

The Leadville District M. & M. Co. is operating a wet-concentration mill, treating about 50 tons of ore per day. The American Zinc Extraction Co. is operating a roaster and magnetic separators, and is shipping about 100 tons per day of zinc sulphide concentrate.

San Miguel County

The Primos Chemical Co. has acquired about 2000 acres of land situated between Fall and Bear creeks, on the south side of the San Miguel river, in the vicinity of Newmire, the tract being within the vanadium belt. This company has under lease the mill of the Vanadium Alloys Co., and is the only concern reducing vanadium ores in Colorado at the present time. The product is bought by the General Vanadium Co. and shipped to Liverpool. The Crucible Steel M. & M. Co., of Pennsylvania, through its agents, J. B. Johnson and R. H. McMillan, has purchased a number of claims on the Vanadium belt, including the Harmon from Tom Bradley, the Gopher from Bradley and Finnegan, the Lone Tree, Jennie Lind, Iowa, Mammoth, and Jumbo from I. B. Imes.

Teller County (Cripple Creek)

The Gold Dollar mines, on Beacon hill, produced 82 carloads of ore during April, and 60 to 80 tons per day have been hoisted and shipped from the Mabel M. and Husted

shafts of this group during May. The Mohawk M. Co. shipped from the Favorite mine, on Bull hill, two cars of ore that sampled $23.40 per ton. The Favorite belongs to the Stratton estate. A mill for cyanide treatment is being erected at the Jo Dandy mine, on Raven hill.

The Mine Rescue Association of Cripple Creek has been formed, the officers of which are as follows: President, Phillip H. Argall, of Stratton's Independence; vice-president, D. D. Woodruff, secretary of the Mine Owners & Operators Association; secretary, Fred Jones, engineer at Portland mine; committee to solicit subscriptions, F. L. Smale, manager at Portland, Dan McCarthy, manager at the Granite mine, and Phillip H. Argall. A rescue station will be established at Cripple Creek, and one at Victor, both of which are to be equipped with appliances required by the U. S. Bureau of Mines.

It is probable that the necessary money to extend the Roosevelt drainage tunnel will be subscribed. The plan is to use diamond-drills in finding other water channels, after which they will be tapped by driving, thus increasing the flow of water from the tunnel, now about 6000 gal. per minute. By this work the water-level in the mines will be lowered more rapidly, and the orebodies now below that level will be made accessible.

IDAHO

Idaho County

The Salmon River M. Co., J. R. Painter, manager, has a large area of placer ground at Eakin bar, on the Salmon river, the camp being 14 miles south of Dixie. Equipment for hydraulic mining and for a hydro-electric power-plant has been shipped from Salmon to Eakin bar, down Snake river, in barges, a distance of 150 miles. Ten barges were brought into use.

Lemhi County

The Pittsburg-Idaho company, owning and operating the Gilmore lead-silver mine, at Gilmore, has five patented claims, employs 65 men, and the property has been developed by a 400-ft. shaft, 3160 ft. of adits, 105 ft. of winzes, 550 ft. of raises, and 1225 ft. of cross-cuts. The total ore shipments amount to 12,122 tons, from the sale of which $203,252 was received. There was a cessation of ore shipments for a few weeks, while some new equipment was being put in position, but they were resumed last month. Over 2000 tons per month are to be marketed at the Salt Lake smelters. J. E. Walker is superintendent.

Owyhee County

The Banner M. Co. is employing about 30 men, and is reported to have put its mill in operation last week. The ore blocked out in the mine is sufficient to supply the mill at full capacity for six months. There is a surface tramway, 1100 ft. long, extending from mill to mine. The property is situated a mile south of Silver City. The mill is equipped with four Nissen stamps, settling-tanks, and concentrating-tables, and the concentrate saved is ground in 6-ft. amalgamating pans for recovering the gold and silver.

Shoshone County

The four principal lead-smelting companies are in keen competition for the purchase of the lead-silver ores and concentrate of the Coeur d'Alene district. This competition, however, is limited by the fact that some of the largest operators are bound by contracts with the A. S. & R. Co., made a few years ago. It is understood that mine operators not held by such contracts are getting a reduced treatment rate. The Salida smelter, and that of the United States company in Utah, receive a fair tonnage of Coeur d'Alene ores, and a new competitor in the district is the International S. & R. Co., which is stocking up with ore at its Tooele plant, pending the building of its lead furnaces. An interesting rumor concerning the lead-mining industry is that lead furnaces are to be built at the big Anaconda copper plant. The existence of competition among the lead-smelting companies is having a stimulating effect on mining in northern Idaho.

MICHIGAN

Houghton County

The Mayflower M. Co., having an area of mineral ground surrounded by the Kearsarge, Old Colony, and Wolverine mines, has sunk a 1300-ft. drill-hole to explore the amygdaloid lode that was penetrated at 1200 ft. on another part of the group, but no ore has been found thus far by the last drilling. Sinking is to be continued. The hopes of this exploration work are based upon what has been discovered on the Old Colony and other adjoining properties.

The Mohawk operations for April showed a recovery of 16.18 lb. of refined copper per ton of ore, which is a gain of 2 lb. over that of March. During that month there was 71,868 tons hoisted, and 63,993 tons stamped.

NEVADA

Churchill County

Work on the Nevada Hills mill is progressing satisfactorily. The steel frame is up, and the covering of corrugated iron, with an asbestos lining, is being put on. The machinery is being put in position, and the 150-hp. double-drum electric hoist for the new shaft was to have been delivered at the mine last week. An electric-driven pump has been put in place in the old workings; and a cross-cut is to be driven from the 570-ft. level to tap the orebody that was opened on the 470-ft. level. The new 3-compartment shaft, now at a depth of 300 ft., is to be sunk to 650 ft., before cross-cuts are driven to the ore. Connections will be made between the old workings and the new shaft, as all ore from both vein systems will be hoisted through the latter. The Nevada Hills mine is at Fairview, the nearest railroad town being Fallon, 36 miles to the northwest.

Esmeralda County

(Special Correspondence.)—At the regular quarterly meeting of the board of directors of the Goldfield Consol-

CLERMONT SHAFT, GOLDFIELD CONSOLIDATED.

idated Mines Co., at Goldfield, May 25, there was declared the regular dividend of 30c. per share, and an extra dividend of 20c. per share, payable July 31, to stockholders who are of record June 30, 1911.

Goldfield, May 25.

(Special Correspondence.)—At the Florence Goldfield mine a station has been cut at the 700-ft. level, and lateral development is in progress on two levels below the 500-ft. Mill-heads have shown a decided improvement with the introduction of ore from the large body opened in the Reilly shoot at the northern extremity of the Florence claim, and the mill is treating 130 tons daily. No concentrate has been shipped recently, as the company's plant now treats mill products as well as the high-grade ore. On the 700-ft. level the south drift will be extended to explore the main Florence and Little Florence veins; these veins formerly yielded high-grade ore to lessees. The large andesite dike, south of Florence hill, will be penetrated in this level in the hope of finding the southern extension of the ore.

Goldfield, May 24.

Eureka County

The Buckhorn Mines Co., owned by George Wingfield and associates, has developed the property by about 12,000 ft. of work. Further improvements are awaiting the rebuilding of the Eureka & Palisade railroad. Fred J. Siebert has charge of the development. At present the property is reached by team or automobile from Beowawe.

Humboldt County

John T. Reid, G. G. Cunningham, and others of Lovelock, are preparing to ship nitrate of soda to California, where it is in demand as a fertilizer. The Lovelock *Tribune* asserts that nitrate shipments from the deposits of that part of the Humboldt valley are likely to increase.

Lyon County

The Mason Valley Mines Co. has given to the A. Leschen & Sons Rope Co., of St. Louis, the contract to erect an aerial tramway from the shipping bins on the Nevada Copper Belt railroad, at Mason, to the No. 4 adit of the Mason Valley mine, the distance being between 5000 and 6000 ft. The tramway is to be ready to operate by Sept. 15. The Mason Valley company is to purchase and set up a new air-compressor at the portal of No. 4 adit. Mason is the new town on the railroad, on the opposite side of Walker river from Yerington.

Nye County

The Tonopah-Belmont Development Co., owner of the Belmont mine, at Tonopah, has received bids and estimates on equipment for a new mill to be erected at the mine. The old mill is situated at Millers, 10 miles from the mine, and the company's plans contemplate eliminating the expense of this haulage of ore. The most important expense to meet under the new arrangement will be to provide for a water-supply. Frederic Bradshaw is the company's manager.

(Special Correspondence.)—The Tonopah Liberty M. Co., operating at Liberty, 18 miles north of Tonopah, recently sent out five bars of bullion, the result of a 10-days run of the mill. The shipment was valued at $10,000. Most of the ore treated is extracted in course of development. About 25 men are employed.

Tonopah, May 27.

W. B. and F. A. Milliken have a force of miners at work developing the Indiana claims at Pioneer. A shaft has been sunk to a depth of 400 ft., and now lateral work in ore is in progress from the 265-ft. station; and a crosscut is being driven to the vein at 400 ft. About 50 tons of ore of milling grade has been hoisted. Some ore shipments are to be made, and it is possible that a mill will be built.

Storey County (Virginia City)

The report of Whitman Symmes, superintendent for the Mexican G. & S. M. Co., for the week ended May 27, notes the cleaning out of the old drain tunnel connecting the Union shaft with the site for the mill which is to be built. On the 2300-ft. level there was hoisted 57 mine-cars of ore, assaying $7.33 per ton, from the north drift off the east cross-cut No. 2, in driving 12 ft. The south drift from the east cross-cut No. 2 was extended 17 ft., and from it 75 cars of ore was taken, averaging $12.21 per ton. Work on the 2400-ft. level consisted of driving 25 ft. on north drift No. 2, starting in the west cross-cut from the north drift, in the course of which there was mined 68 cars of ore averaging $16.50 per ton. On the 2500-ft. level, work was done on the third and fourth floors of the stope at the end of the north drift, from which 94 cars of ore of an average value of $70 per ton was mined. Three railroad cars of first-grade ore were shipped to the smelter.

The report of T. F. McCormick, superintendent of the Con.-Virginia mine, for the week ended May 27, gives account of work on the fourth and fifth floors in the stope above the 1750-ft. level, where there was mined 145 tons of ore averaging $10.90 per ton. On the 2450-ft. level the west cross-cut, started in the south drift, 280 ft. in from the mouth, was advanced 15 ft., making a total length of 47 ft. Work on the 2550-ft. level consisted of driving 21 ft. on the west cross-cut, from the southwest drift that was started from the north boundary of the mine. There was shipped 130 tons of ore to the Comstock tunnel mill at Sutro.

Work in the Ophir mine for the same week was mostly on the second, fourth, eighth, ninth, and tenth floors in the stopes above the 2100-ft. level, and from these workings there was extracted 262 tons of ore, assaying $44.94 per ton. This work was in the west cross-cut, started in the main northeast drift 200 ft. north from the south boundary of the mine. The ore shipped to the Kinkead mill amounted to 341 tons; one railroad car of concentrate was shipped to the Selby smelter.

White Pine County

The Kinsley Development Co., mining in the northeastern part of this county, shipped 26 tons of ore to a Salt Lake smelter which sampled 22 oz. silver and $1.42 gold per ton, 21% lead, 40% iron, 11% silica, 1% sulphur, 1% zinc. A carload of copper was more recently shipped from another part of the same property. The camp is nearly west of the Deep Creek district, in Tooele county, Utah.

NEW MEXICO

Grant County

The Western Belle mines, Pinos Altos district, are being operated with a force of 60 men, by McKinney, Corrigan & Hutchinson. The properties include the Hearst and Gillette. The 500-ft. shaft on the former was retimbered last spring, and the shaft on the latter has reached a depth of 800 ft. The lateral development from these shafts is mostly in ground previously unexplored, a body of high-grade ore having been opened on the 400-ft. level of the Hearst mine.

The Chino Copper Co., it is estimated, has 45,000,000 tons of ore developed, 70% of which can be mined by the steam-shovel method. The ore assays about 2.3% copper. The properties are at Santa Rita.

Socorro County

(Special Correspondence.)—The oil consumption for power purposes at the mill of the Deadwood mines, Mogollon district, is said to be less than 11c. per horse-power day, and since not to exceed 70 hp. is required to handle 50 tons daily in this mill, the fuel cost to crush, stamp, and treat a ton of ore is less than 16c. To this must be added cost of labor, depreciation, and other items in arriving at the total power-cost which is under 50c. per ton. The mine has been unwatered to the second level; ore is being supplied to the mill from this and the first levels. The large accumulation of water in the lower workings will be permitted to stand until the water-supply, from springs two miles up the canyon, is tested during the normally dry months of May and June, and will be drawn upon for ore-treatment if necessary.

Mogollon, May 30.

OREGON

Josephine County

The Waldo Con. Gold M. Co., having 4353 acres of placer ground in the vicinity of Waldo, and controlling the water rights on the east fork of the Illinois river, operates on an extensive scale, with modern equipment. These holdings comprise the various groups which were consolidated, including the Osgood, Logan, Deep Gravel, Freye Gulch, and Frainey. The operations consist of hydraulic work with giants, drift mining from shafts sunk to bedrock, and with hydraulic elevators. A 1-mile tunnel is to be driven from the head of Butcher gulch to the Deep Gravel mine, to be used as an outlet race for carrying away the tailing from the Logan mine, thus making the hydraulic elevator unnecessary at this property. It is stated by the Grants Pass *Courier* that a dredge is to be built this season for operating on the Deep Gravel mine. The operations of the company are under direction of Frank M. Leland.

The Oriole mine is opened by adits No. 1, 2, 3, and 4, which, with the cross-cuts, drifts, and winzes, amount to one mile of development. No. 4 is the main working level,

and this attains a depth of 600 ft. on the vein. The ore is to be hauled to the mill over a surface tramway by gravity. The grade of the selected ore is demonstrated by four shipments made to the smelter at Tacoma, the net returns from which showed about $200 per ton.

The Oscar Creek Con. M. Co. has acquired 250 acres of placer ground on Oscar creek, 10 miles south of Grants Pass. The group is made up of a number of smaller holdings that formerly were worked by individuals. The principals in the company are A. H. Gunnel, L. L. Jewell, and Charles Burkhalter, all of Grants Pass. The intention is to provide equipment to operate on a larger scale.

The properties of the United Copper-Gold Mines Co., formerly controlled by O. H. Thomas, F. E. Newberry, O. S. Blanchard, and Ralph Looney, have been taken over by South Dakota men, comprising W. L. Low, G. C. Westby, James Greig, and George Williamson. Mr. Low formerly operated in British Columbia, and Mr. Westby is a metallurgist, who formerly was in Nevada. The holdings purchased consist of quartz claims on Pickett creek, 7 miles west of Merlin, and a group of 8 claims on Illinois river, 12 miles northwest of Selma. The first work to be performed will be on the latter group, where a vein of copper ore was developed by former operators.

UTAH

Beaver County

(Special Correspondence.)—South Utah Mines & Smelters has issued a report on April production which shows a decrease in tonnage as compared with March, but a higher production of metal. The figures are: Tons ore, 21,743; tons concentrate, 1969; pounds copper, 300,137; ounces gold, 145; ounces silver, 2690. March figures were: Tons ore, 23,972; tons concentrate, 2301; pounds copper, 300,007; ounces gold, 141; ounces silver, 2583. The average tonnage treated in April was 720, which has been increased during May to about 800.

Newhouse, May 27.

Juab County

The Southern Eureka group of 80 acres, close to Mammoth, which was partly developed by a 500-ft. shaft, is to be further developed through a deep shaft on the Opex. Among those interested in it are S. D. Nicholson and C. T. Limberg, of Leadville, and J. H. McChrystal of Eureka, who are arranging to have work commenced. E. R. Higginson, having a lease on a block of ground in the Black Jack mine, has been mining on a stringer of gold ore, a carload shipment of which sampled 5 oz. gold per ton, and this was accompanied by some silver. V. Whiting, also a lessee on the Black Jack, is making regular shipments of iron ore, on which he realizes a small profit.

Salt Lake County

The Utah Apex development during the last five months has resulted in opening a body of lead ore approximately 50 ft. wide, and driving thereon has demonstrated the length, thus far, to be 400 ft. This orebody was opened by driving from the main haulage-level. The operators of the property are shipping 125 to 150 tons of ore daily from the drifts and stopes of the new workings. While running high in lead, this ore contains an excess of iron.

WASHINGTON

Ferry County

(Special Correspondence.)—The Belcher mine is employing 20 men, with W. M. Anderson as superintendent, and is shipping from 50 to 70 tons of ore per day to the Granby smelter, under a contract to deliver 12,000 tons. The ore contains an average of 50% iron and 35% sulphur. Five Leyner drills are in use, driven by a compressor at the Spuro mine, 6000 ft. distant. The No. 3 adit-level is 750 ft. above the Belcher mountain railway track, and the ore is delivered from the portal of the adit by an 1875-ft. gravity tramway. The ore is drawn from the 200-ft. and intermediate levels, where the vein is 60 ft. wide, the stoping being from wall to wall. A raise has been driven from No. 3 level to the intermediate. The mine has in sight, and partly blocked out, about 100,000 tons of iron carbonate and an equal tonnage of sulphide ore. The ore contains low value in gold and traces of copper. After the mine had been idle over a year, percolating water dropping on the floor of the No. 2 adit-level precipitated sulphate of copper. Copper-bearing ore was formerly shipped from the No. 3 level by J. L. Harper, the former manager, whose predictions regarding the Belcher mine are now being realized.

The Great Northern Railway Co. has put into effect a freight rate of $4 per ton on ore from Republic to the Washoe smelter, Anaconda, Mont. The Granby company being unwilling to receive Republic ore during the coke shortage, Mr. Harper, of the Republic Mines Corporation, arranged with the Washoe smelter people for the shipment of ore from the Republic mines in which he is interested.

Republic, May 25.

King County

The Seattle-Cascade Mining Co., after having developed a mining property in the vicinity of Berlin, has purchased equipment for a concentrating mill, the foundation for which has been laid.

Okanogan County

(Special Correspondence.)—The property of the Double Header M. Co. is situated at Nespelem, 2½ miles from the Columbia river, making easy transportation by boat to Wenatchee. Development has resulted in exposing silver ore in two veins. A large percentage of the ore is of good milling grade, while a portion of it assays over $100 per ton. A 2-compartment shaft was sunk 80 ft., drifts from which were extended to both veins. It is the intention to sink 100 ft. deeper. As soon as the mine is well developed a mill is to be built. The work is in charge of George McQuinn, of Seattle.

Nespelem, May 11.

Stevens County

(Special Correspondence.)—The Oriole M. Co. has two carloads of ore ready to ship from its mine at Metaline. It is made up of two classes of ore—one in which gold is of principal value, and another which consists mainly of lead. The mine has been opened by a cross-cut to the ore, on which there has been several hundred feet of driving and winze work. A second cross-cut is being driven whereby the vein is to be opened 200 ft. deeper. Joseph Lancaster is engineer in charge of the work.

Metaline, May 6.

MEXICO

The Pearson oil interests are now furnishing fuel oil to the Mexican railway, operating between Mexico City and Veracruz. A contract to furnish fuel oil was entered into by the Pearsons a few years ago, but their failure to develop sufficient supplies made it impossible for them to fill it, and the failure proved expensive. Recent developments in Veracruz have given the Pearsons a big supply of oil, and the contract has been renewed.

Chihuahua

(Special Correspondence.)—The March operations of La Republica Mining Co., as reported by J. Gordon Hardy, consulting engineer, of El Paso, Texas, are summarized as follows: Ore milled, 1224 tons; gross production, ₱76,710.99; operating charges, ₱46,834.79; construction expenses, ₱3369.84. The mine is at Sanz, reached by way of Ocampo.

Ocampo, May 2.

San Luis Potosi

The Benito Juarez mine, situated ten miles south of Salinas, was raided by a body of bandits recently, who forced those in charge to close down the mine and stop the pumps. As a consequence the mine workings were flooded with water, entailing heavy damages. Americans and one Englishman, connected with this and other mines, were robbed of their money and stores, and subjected to rough treatment. The Benito Juarez is owned by a company for which A. B. Carpenter is engineer in charge.

Company Reports

TENNESSEE COPPER CO.

The Tennessee Copper Co., operating in Ducktown district, with offices at Copperhill, employs 1000 to 1200 men. Its gross earnings for 1910 were $547,157, an increase of $119,502 over those of the previous year. The net earnings amounted to $445,387, being $105,982 in excess of those of 1909. The production of copper for the year was 12,429,009 lb., which is 1,500,000 lb. less than the output of the last year; the principal increase in profits was due to the manufacture and sale of sulphuric acid. The cost of copper production for 1910 was 10.6c. per pound; the dividends paid amounted to $300,000. The ore available in the mine on December 31 was estimated at 4,563,671 tons, which is said to be greater than has been shown at any former date. It is estimated that the profits from the operation of the acid plant during 1911 will reach $500,000.

NEW YORK & HONDURAS ROSARIO MINING CO.

This company, with properties at San Juancito, Honduras, in its thirty-first annual report for the year ended November 17, 1910, gives the following table of production, extraction, and costs for the year:

PRODUCTION

Ounces silver produced	1,289,173.87
Ounces gold produced	102,610.82
Ounces silver produced per ton	35.19
Ounces gold produced per ton	0.289
U. S. value of total	$857,008.59
Production per ton	$23.39
Pesos value of total at 170%	2,313,923.19
Production per ton, pesos	63.163
Total tons crushed during year 1909-1910	36,634.55

EXTRACTION

	Percentages of Extraction.
Silver	86.17
Gold	89.68
Total	87.73

COSTS

	Labor		Supply	
	Total.	Per ton.	Total.	Per ton.
	₱	₱	₱	₱
Mine	525,948.78	14.36	177,672.38	4.85
Tramway	37,034.37	1.02	17,993.49	0.49
Mill	75,015.35	2.05	258,346.03	7.05
Surface improvement	169,687.85	4.62	22,967.70	0.63
Total	807,686.35	22.05	476,979.60	13.02

TOTAL

	Total.	Per ton.
	₱	₱
Mine	703,621.16	19.21
Tramway	55,027.86	1.50
Mill	333,361.38	9.10
Surface improvement	192,655.55	5.25
Total	1,284,665.95	35.06

Thirteen veins are being worked, the most important being the San Miguel and the ore reserve is estimated at 107,575 tons (containing an average of 23.7% waste) of an average gross value of $25.30 per ton, or a gross value of $2,776,437. The operating profit for the year ended September 30, 1910, was $349,476. During the year six dividends were paid, amounting to $105,000, leaving a balance on hand, October 1, 1910, of $1,429,150. The amount of capital stock is $1,500,000, and the surplus is given as above. The bullion production since 1882 is given as $15,530,574. One hundred and seventy dividends have been paid, amounting to $2,970,000 in all.

Book Reviews

Any of the books noticed in these columns are for sale by, or can be procured from, the MINING AND SCIENTIFIC PRESS.

QUALITATIVE CHEMICAL ANALYSIS OF INORGANIC SUBSTANCES. By O. F. Tower. Pp. 84. P. Blakiston's Son & Co., Philadelphia, 1911. For sale by the *Mining and Scientific Press*. Price, $1.

This is a student's text-book and pre-supposes considerable familiarity with general chemical principles. It is brief, well arranged, and clear.

WINDMILLS AND WIND MOTORS. By F. E. Powell. Pp. 78. Pocket size. Ill. Spon & Chamberlain, New York, 1910. For sale by the *Mining and Scientific Press*. Price, 50 cents.

This is a simple treatise on how to build and run wind engines. It discusses principles briefly, and gives detailed drawings showing how to construct small mills. Considering the long use of windmills and the wide territory in which they can be used, it is surprising that so few works in this field are available. Wind-power is readily available at many isolated mines where a small amount of power would be of great service, and is more reliable than is often supposed. To engineers finding themselves in such a place this little book will be particularly useful.

DREDGING OF GOLD PLACERS. By J. E. Hodgson. Pp. 65. Ill. Sir Isaac Pitman & Sons, Ltd., London, 1911. For sale by the *Mining and Scientific Press*. Price, $2.

This, the latest addition to the growing literature of dredging, is based upon experience principally in the Ashanti fields, with extensive observation elsewhere and wide reading. Mr. Hodgson gives many practical suggestions, and the book is quite worth reading. It is more incidental than comprehensive in treatment and lacks any adequate description of the dredges themselves, comparative tables of performance and costs, wholly ignores methods of hand-drilling, and is weak in its treatment of American dredging practice. It is, however, frank, and generally accurate, and will be of value to American engineers in giving them side-lights on foreign conditions and work.

H. F. B.

THE MINES DIRECTORY. Vol. 1, 1910. Pp. 610. Pub. by The Mines Directory Co., Salt Lake, Utah, 1911. For sale by the *Mining and Scientific Press*. Price, flexible back, $7.50; cloth, $5.

This is a directory of the metal mining companies of the Western States, including Arizona, California, Colorado, Idaho, Montana, Nevada, and Utah. In addition, a limited number of companies operating elsewhere are included, as are also tables of statistics and a summary of mining laws. The directory is the most valuable part of the book. While inaccuracies and omissions will doubtless be found, the book will none the less be extremely useful and corrections can be made in future editions. We hope every user of the book will supply the publishers with additional data, so that in time a comprehensive and accurate annual may be available.

OIL AND PETROLEUM MANUAL, 1911. By Walter R. Skinner. Pp. 164. Published by the author, London, and for sale by the *Mining and Scientific Press*. Price, $2.

The second annual issue of this handbook prepared by Walter R. Skinner, is now available. It contains full particulars of nearly 500 companies, in addition to the names and addresses of (1082) directors, (262) secretaries, (113) consulting engineers, managers, and agents. The particulars given regarding each company include the directors and other officials, date established, situation of property, purchase consideration, royalties payable, number of wells sunk, output, and description of work in progress, capital, if offered to the public, calls, dividends, and financial position as disclosed by accounts, also latest price of shares. The book is a companion volume to the well known 'Mining Manual,' also published by Mr. Skinner.

Personal

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

W. H. Weed is at Porcupine.

W. H. Aldridge is in the East.

Sumner S. Smith is at Pittsburg.

George S. Rice sails on June 17 for Europe.

O. B. Perry was in San Francisco last week.

Arthur G. Blake has gone to Nome, Alaska.

Harry Johnson is studying the Oklahoma oilfields.

L. D. Ricketts was at the Miami copper mine May 26.

Silas L. Gillan is at Globe, Arizona, for the Land Office.

H. F. Julian sailed on the *Mauretania* May 24 for London.

Chester B. Naremore is now with the Valeeitos Oil Company.

S. W. Mudd has been visiting the Chino and Ray copper mines.

R. M. Haskell has returned from Triunfo, Baja California.

M. K. and J. H. Rodgers, of Seattle, were in San Francisco, May 29.

Dietz & Keedy, of Boston, have recently made examinations in Maine.

J. Nelson Nevius has returned to Los Angeles from southern Utah.

James W. Malcolmson, of Kansas City, was recently at Ketchikan, Alaska.

T. Walter Beam, of Denver, visited Republic, Washington, last week.

E. L. Dufourcq was in San Francisco and has gone to Shasta county, California.

F. H. Probert, who has been in New York and Chicago, is returning to Los Angeles.

Alexander Leggat has gone to Alaska to report on copper prospects to the west of Cook Inlet.

Courtenay De Kalb is at Tucson, Arizona; will be in Los Angeles June 10, and then in Mexico City.

H. Cushing Smith has accepted the management of the Wettlaufer-Lorain silver mines, in the Cobalt district.

J. F. Callbreath is making a trip through southern Alaska, expecting to visit Juneau, Cordova, and Valdez.

D. M. Riordan and J. B. Keating, of the Bully Hill Copper M. & S. Co., recently visited the properties of that company in Shasta county, California.

M. H. Kuryla, formerly in charge of milling operations for the Esperanza Mining Co., is now with the Merrill Metallurgical Co. at the new Santa Gertrudis mill, Pachuca, Mexico.

Obituary

William McHale, one of the best-known old-time prospectors and mining men in the West, died recently at Florence, Arizona. Mr. McHale was a native of Pennsylvania, served in the Civil War, and has spent his time since then on the plains and mountains of the West. He has made several fortunes, and at 64 years of age he was tramping the hills in preference to enjoying the luxuries which he had the money to buy. He was the owner of mining property in Utah, Arizona, Nevada, and California.

Charles D. Lane, who died at the age of 72 years in his home at Palo Alto, last week, was long a prominent figure in mining circles on the Pacific Coast. Born in 1840, in Missouri, he drifted into mining on the Coast, and, with Hayward and Hobart, developed the Utica mine at Angel's Camp, and more recently was prominent in the development of the Seward Peninsula and the construction of the railroad from Nome to Anvil creek.

Decisions Relating to Mining

Specially reported for the Mining and Scientific Press.

Taxation of Oil—Interstate Commerce

Oil pumped from a pipe-line from one State to a point in another, is a subject of interstate commerce and is therefore exempt from local taxation.

Prairie Oil & Gas Co. *v.* Ehrhardt, (Illinois) 91 Northeastern, 680.

Location of Mining Claim—Effect of Excess

A placer-mining claim located in good faith is not wholly void merely because it exceeds twenty acres. In such case it is void only as to the excess, and this may be rejected from any portion the owner may select, and until he has been advised of the excess and has had a reasonable time to make his selection, his possession extends to the entire claim, and a third person who makes a location of any part of such claim is a trespasser and his location is a nullity and is void for any purpose.

Jones *v.* Wild Goose Mining & Trading Co., 177 Federal, 95. March 1910.

Taking Ore Without Consent—Measure of Damages

The measure of damages for unlawfully taking ore from a mine, but which taking is done in good faith under the belief that such ore belonged to the person taking the same, is the value of such ore as it was in the mine before mined or undisturbed. As applied to the taking of oil, the measure of damages for taking of oil from land through mistake as to its ownership is the value of such oil at the surface or in tank less the cost of pumping and tanking it, and not the usual royalties for producing oil.

Bender *v.* Brooks, (Texas) 127 Southwestern, 168. April 1910.

Conveyance of Land—Reservation of Oil

A deed conveying certain land excepted and reserved out of and from the grant at all time thereafter and forever unto the grantor, his heirs and assigns, one-tenth of all the gas and oil that might be obtained by the grantee, his heirs and assigns, from the land granted, the same to be delivered on the land to the grantor or his agents, free of expense, except the furnishing of barrels or other means of transportation. In an action for an accounting, the effect of this reservation was to reserve in such grantor, his heirs and assigns, to be delivered as stipulated, a royalty of one-tenth of all the oil produced, possessing the same quality of estate as royalty reserved in an ordinary lease for oil and gas purposes.

Jackson *v.* Dulaney, (West Virginia) 67 Southeastern, 794. March 1910.

Failure to Contribute to Assessment Work—Right of Forfeiture

The publication of notice to a part owner of a mining claim to contribute to the cost of doing assessment work thereon for the previous year under penalty of forfeiture of his interest under the statute, is a waiver of a prior personal notice to the same effect, and the delinquent may make his contribution at any time within 90 days from such notice by publication. A part owner of a mining claim who holds an option to purchase the interest of his co-owner has a right to pay or tender the contribution of such co-owner to the cost of the assessment work to avoid a forfeiture; and a failure to object to such tender on the ground of want of authority of the agent when made is a waiver of the right to make such an objection. The rule is that one who does assessment work on an association place or mining claim for which he is paid by one of the part owners has no right to enforce a forfeiture of the interest of another part owner for failure to contribute.

Kniekerboeker *v.* Halla, 177 Federal 172. Feb. 1910.

Magnesite, brick (see firebrick).		
Manganese ore, oxide, crude, per ton	10.00	25.00
Manganese, prepared, according to quality, per ton	40.00	120.00
Mica, according to size and quality, per lb	0.05	0.30
Molybdenite, 95% MoS_2, per ton	400.00	500.00
Monazite sand (5% thoria), per ton	150.00	200.00
Nickel metal, refined, per lb	0.45	0.60
Ochre, extra strength, levigated, per 100 lb	2.25	3.25
Platinum, native, crude, per oz	25.00	30.00
Scheelite (see tungsten ore).		
Sulphur, crude, per ton	15.00	25.00
Talc, prepared, according to quality, per ton	20.00	50.00
Tin ore, 60%, per ton	450.00	475.00
Tungsten ore, 65%, per ton	487.00	520.00
Vanadium ore, 15%, per ton	200.00	250.00
Wolframite (see tungsten ore).		
Zinc ore, 50% up, per ton	*15.00	20.00

Commercial Paragraphs

H. D. McLeod, of Cleveland, Ohio, is now connected with the Seattle Machine Works, where he is having the McLeod concentrating table built.

The Mine & Smelter Supply Co. announces the appointment of William D. Gordon, late of South Africa, as local manager of its branch house at El Paso, Texas.

Abbe Engineering Co. has moved to larger quarters at 220 Broadway, New York, and the increased space will enable it to exhibit a number of additional mills in the showroom.

W. M. White, formerly of the I. P. Morris Co. of Philadelphia, has become associated with Allis-Chalmers Co. as manager and chief engineer of their hydraulic turbine department.

The Way's Pocket Smelter Co. of South Pasadena, Cal., reports that the sale of its pocket smelter outfits, as well as its whole line of miners' supplies, has greatly increased during the past month.

The Redwood Manufacturers Co., has moved its tank and cyanide plant equipment department from its factory at Black Diamond, Cal., to room 916 Balboa building, San Francisco, Cal., adjoining the wooden pipe department which has been at this address for some time.

Meese & Gottfried Co. of San Francisco, Seattle, Portland, and Los Angeles, are giving away a convenient pocket catalogue of 300 pages, covering their line of transmission, elevating, and conveying machinery. It is a compact and valuable reference book for engineers.

Woodin & Little, San Francisco, are distributing their catalogue No. 35, covering pumping machinery of all kinds, gasoline engines, and windmills. This company is one of the pioneer houses of the Pacific Coast and, as in the past, their catalogue is replete with excellent illustrations and complete information, with dimensions of their machinery.

The New York Metal Hose Co., 42 Broadway, New York, is producing a flexible metal hose up to 12 inches internal diameter for use with high-pressure steam, petroleum, and gasoline, or for suction hose in phosphate mines, rock drills, water, and compressed air, and all purposes where a flexible connection is desired. They claim this hose will stand any reasonable amount of heat and the action of oil. The U. S. Navy uses it for charging torpedoes for a pressure of 4000 pounds per square inch. For steam use the ends or the entire length is covered with asbestos and cotton fabric to permit handling.

Falkenburg & Laucks, of Seattle, Wash. have built an ore-testing plant at an expenditure of nearly $6000, in which they have good facilities for making tests of ore in carload or smaller lots, by amalgamation, concentration, and cyanidation. The plant occupies two floors of a building 36 by 74 ft., and the equipment comprises a 7 by 8 crusher, a battery of one 1300-lb. Nissen stamp, amalgamating plates, Wilfley and McLeod tables, tube-mill, Callow tanks, one Pachuca agitating tank, and sampling devices. It also contains a rotary kiln for cement testing, and a Reihle 2000-lb. machine for testing steel. The plant is on the tide-flat, has railroad shipping facilities, and is close to the water channel that connects with the bay.

F. E. Marcy, formerly district manager for Allis-Chalmers Co. at Salt Lake, has become associated with The Mine & Smelter Supply Co. as manager of its business at Salt Lake. During the last six years Mr. Marcy, while acting as manager for the Allis-Chalmers Co., has been closely in touch with the metallurgical development of this country, and has designed some of the largest equipment, among which may be mentioned McDougall furnaces for the Garfield Smelting Co., converter equipment for the First National Copper Co., copper converters for the Canadian Copper Co., copper converters for the United States S. R. & M. Co., at Kennett, Cal., and McDougall furnace equipment for the Steptoe Valley S. & M. Company.

The Williams Patent Crusher & Pulverizer Co. of St. Louis, Missouri, is sending out the following notice: "The United States Circuit Court of Appeals at Philadelphia rendered its final decision in the suit that we brought against the Pennsylvania Crusher Co. some time ago for infringement of our patent, No. 843,729, for improvements in dumping cages for crushers and pulverizers. This decision of the Court of Appeals handed down in the March term, 1911, concludes 'the record will be remanded with instructions to the Circuit Court to enter a decree reversing the former one adjudging claims 1 and 2 of the patent in suit to be valid and infringed and awarding to the complainant an injunction with the usual accounting and costs of suit.'

"Under the law, a user of an infringing machine is liable for his acts of infringements. The maker and seller of the infringing machine in question has been found to have infringed our patent, No. 843,729, and the Court of Appeals, in addition, has found the infringed claims of said patent to be valid.

"It is our intention to protect our rights as secured to us by the above patent and numerous other patents which have been granted on improvements we have made in crushing and pulverizing machinery, and the public is warned against buying crushing and pulverizing machines which infringe any of our 87 patents."

MINING AND SCIENTIFIC PRESS

"Science has no enemy save the ignorant."

Whole No. 2655 VOLUME 102 NUMBER 23 | SAN FRANCISCO, JUNE 10, 1911 | THREE DOLLARS PER ANNUM Single Copies, Ten Cents

Entered at San Francisco Postoffice as Second-Class Matter.

TABLE OF CONTENTS

EDITORIAL

CANADIAN RECIPROCITY now holds the attention of Congress, and the issue is still in doubt.

SHARES in many American corporations have been listed on the Paris Bourse and London Exchange recently, a late addition being American Smelting & Refining Company.

THE first of the postal savings bank bonds will be issued soon. These will be in denominations of $20, $50, and $100, bearing 2½ per cent interest, and undoubtedly will prove popular.

THE March record in the work of excavation in the Culebra cut was a notable one. Handling material of which 70 per cent was solid rock requiring blasting, the 50 steam-shovels averaged 1430 cubic yards per day, at a direct cost of 37.65 cents per yard, and a total cost of 51 cents per yard.

OFFICIALS of the American Mining Congress are now jubilant at having secured from President Taft a promise to attend the forthcoming meeting in Chicago, beginning September 25. Mr. Walter L. Fisher, Secretary of the Interior, is also expected to attend, and the meeting promises to be a most interesting one.

WELCOME NEWS to the graduates and undergraduates of the Massachusetts Institute of Technology is that T. C. Du Pont has given a half million dollars to be used toward the purchase of the new site which has so long been needed. A further grant of $100,000 a year for ten years from the State gives needed aid toward the solution of the problem of expansion.

THE problems arising out of the amalgamation of Asiatic, Ethiopic, and Caucasic races in the Hawaiian Islands have recently been discussed by Mr. J. L. Kelly in the *Westminster Review*. These are only a few of the questions growing out of the changes which have taken place in the countries bordering on the Pacific in recent years, and next week we expect to discuss some of them at greater length.

WE PRESENT this week the concluding article of Mr. J. W. Hutchinson's series descriptive of the work of the Goldfield Consolidated mill. The great productiveness of this mine has made it such a source of interest that the noteworthy metallurgical work done there has been somewhat overshadowed. The thanks of the profession are due to Mr. Hutchinson, as is evidenced by the great amount of interest and commendation which his articles have evoked.

SAMPLING and assay methods vary greatly from place to place and there is a lack of uniformity that is provocative of much friction and misunderstanding. The U. S. Bureau of Mines is planning an investigation of the methods of cargo sampling of ores and metallurgical products and as a first step, Mr. J. A. Holmes, the director, has been conferring with a number of engineers engaged in commercial sampling.

CABLE rates from the United States to Brazil have been lowered by the Postal Telegraph Cable Company. This is an excellent method of stimulating trade between the two countries. It is interesting to note, however, that the messages cross and re-cross the Atlantic going "via Azores."

THAT the United States battleship *Delaware* will be the largest warship present at the naval review held in connection with the coronation ceremonies of King George V, is surprising news to many Americans, who are more often accustomed to hear our navy spoken of in terms the reverse of laudatory, and illustrates that though our Nation is negotiating general treaties of arbitration, it is not unprepared for war.

THE decision of the Supreme Court in the Tobacco case, which was handed down last week, extends and strengthens the results achieved by the preceding decision. In brief, the monopoly now existing must be dissolved and competitive conditions restored. There must be real and complete disintegration. How this is to be secured is yet to be determined. One result is sure, there is now no uncertainty as to what the law will allow, and plans for the future can now be made.

INCREASED consumption of copper would relieve the present difficulties of copper producers. Mr. Alfred C. Lane points out in a letter to the *Boston Transcript* that a considerable increase could easily be brought about if architects would use copper more extensively for roofing. That they do not do so is due partly to lack of information and partly to the fact that the price of sheet copper has not gone down in the same ratio as has the price of wire. A little intelligent attention to the matter would seem worth while.

THE BUREAU OF MINES has just sent forth No. 1 of a series of 'Technical Papers,' a discussion of 'The Sampling of Coal in the Mine' by the Director, J. A. Holmes. The value of information is immensely increased if it is presented promptly. A hastily prepared plan of campaign before the battle, is of incalculably more value than a scholarly analysis of it a year later, and in thus presenting at the earliest feasible moment the results of investigations by the Bureau of Mines, the greatest effectiveness will be secured and the greatest good subserved.

THE POSTOFFICE DEPARTMENT, in a preliminary announcement, predicts that the accounts for the year ending on June 30, next, will show a surplus of receipts over expenditures of more than a million dollars, and the Postmaster General has returned to the Treasury $3,000,000, which was set aside from the public fund to make good the usual deficit in the operation of that department. Second-class rates have not been raised, the rural free delivery service is still in operation, and we have postal savings banks. Mr. Hitchcock has therefore demonstrated one thing that the department needs; the introduction of business methods of administration.

CLIMATE has an effect on trade, as is interestingly illustrated by the growing use of metal ceilings and storefronts in Hongkong. Almost all the buildings erected there by foreigners have steel beams, and the Chinese are beginning to use them as well. The white ant destroys wooden beams and the woodwork of ceilings to such a degree that steel is preferred, even where labor and plaster are both cheap. The objection to steel is the humidity of the climate, causing deterioration due to rust. Consequently even building hardware is made almost entirely of brass, which, when locally manufactured, is cheap but of inferior quality.

A PROFIT-SHARING SYSTEM for the more than a half million employees of the National Electric Light Association was proposed at its recent convention, as well as plans for insurance and saving funds for employees.

INSTEAD of always trying to 'hustle the East' it would often be well to learn of her wisdom. About twenty-five years ago, when one of China's most faithful officials was warden of the Eastern Marches, and Taotai at Fenghuangcheng in Manchuria, he decreed that all hillsides which could not be permanently used as farm land and pay taxes, must revert to the Government, unless the nominal owners planted them with trees. Then regular title deeds would be given, with all rights secured, and the planted hills would be free of all tax for a number of generations. In consequence the hills were soon covered with fir, silkworm oak, and other trees. The villagers have plenty of fuel from the undergrowth, and the valleys are growing richer harvests. Japan might do well to follow this example, in her government of Korea. The Koreans have used wood as fuel exclusively and for centuries they have felled the forests and have even dug up the roots, so that now in rainy seasons the soil offers no resistance, and every year the area of agricultural land decreases.

A Defense of Prejudice

Recently there have appeared, in contemporary journals, notices of a book bearing a title similar to that above. We have not read the book—no defender of prejudice would ever stop to read a book before expressing an opinion of it—but to us the idea appears excellent. Prejudice is commonly reckoned as a vice, but, to paraphrase Stevenson, the wise man may well hesitate to draw the line between vice and virtue. We dare affirm that if such a line can be drawn, prejudice will be found on both sides of it. In so far as prejudice is a vice it is not an ugly one. To believe that the antagonist is a poor sort of fellow with no redeeming feature; that the other side of the case has not a single good argument to sustain it; that any other method than the one advocated will result in disaster, is a vice, but a full-blooded, human kind of vice, that is easily forgiven. And the belief that our country is the best place in the world to live, our city in some degree the best in the country, our employment the most useful and honorable, and our own people the best there are, is a virtuous prejudice out of which fidelity and devotion grow. It is curious that the philosophers, Epictetus, and all the rest, have held before us as an ideal the calm judicial temperament that in real life often proves cold and unattractive. Many of the most useful, best loved, and best hated men of the ages have bristled with prejudices; and the man who claims to be free of prejudice usually has a prejudiced view of his own excellences. If he is honest with himself every man is a defender of prejudice.

Institute Changes

At a joint meeting of the Council and Board of Directors of the American Institute of Mining Engineers, in New York last month, a set of regulations for the formation of local sections of the Institute was adopted and the applications from San Francisco and New York for permission to form local sections were granted. The most important features of the regulations governing local sections are that they must consist of at least twenty-five members, and that all the members of the Institute who reside within the territory of the section shall be members of the section, which shall include no others. The Institute may contribute toward the support of its branches and papers presented before the sections shall be the property of the Institute.

The formation of sections is a most commendable innovation. In agriculture it is customary to carefully cut away all the shoots about the base of the main stem of a plant, so that the strength of the roots may be concentrated into a larger growth of the single stem. But the agricultural analogy does not hold when applied to scientific societies. A better analogy is with politics, where each local organization serves as a stimulus to greater interest in national questions, and it can not be doubted that the influence exerted by local branches of the parent society will be for the good of both.

The suggested change of name of the Institute to include metallurgy should receive careful consideration. At the time of the founding of the Institute metallurgy was so little developed compared with the present that it was naturally not included in the name chosen. At the then recently formed Columbia School of Mines metallurgy was taught by Thomas Egleston, who was also professor of mineralogy. Now in our schools, metallurgy constitutes a separate department, often a separate course, and its literature is more voluminous than that of mining. Logically mining and metallurgy should be treated separately, since the one is based upon physics and the other upon chemistry. But an old and well known firm does not change its name every time a new partner is taken into the business, for obvious reasons; reasons that may well apply to the case of our Institute. From the fact that metallurgy by nature lends itself more easily to scientific experiments and discussions, it has always received its due share of space in the *Transactions*, and it may well be questioned whether it is now worth while to signalize in the proposed manner a change that has been the slow growth of years.

National Problems

In his able and thoughtful discussion of the rights and duties of the individual, State, and Nation, in the use and conservation of mineral resources, Mr. J. A. Holmes has touched on many things that can with great profit be given serious consideration by our readers. That the needs of the Nation will increase much faster than the rate of increase of population can scarcely be over-emphasized. The ordinary citizen of today not only has, but demands, utilities and conveniences that were undreamed of by his great-grandfather. The daily wage of a laborer now enables him to command the services of railroads and tramways, steamships, telegraphs, telephones, electric and gas light and power, printing presses, and a host of other industries that spring directly from the loins of mineral production, in a way that would have appeared incredible even a generation ago. Take a concrete example. In so high a type of civilization as the Chinese people enjoyed before the introduction of foreign devices, a few decades since, the needs of the people made necessary a production of not more than one pound of iron per capita per year. The present needs of the American people make necessary, for domestic consumption, a yearly per capita production of approximately 675 pounds of iron. No more striking illustration of the relative utilities and conveniences now available to the average citizen of the two countries could be desired. How much the needs of our population are likely to further increase is difficult to say. This much is certain from past experience; we cannot hope to decrease our needs, but we are assuredly decreasing our present reserves. This does not mean that it is necessary to be despondent over the future. Great additional reserves can be added to those existing by improvements in methods that will make available what is now useless. The skill of man has always been adequate to his needs, and it is not too much to believe that it will continue to be. The problems need, rather, adequate prevision. Our national life now moves with such express speed that its leaders must scan the future closely, just as an engineer keeps keen watch ahead, so that he may shut off steam and apply the brakes long before an obstacle is reached. The history of civilization is a history of achievement by mankind of what had been deemed impossible. With sufficient thought for the morrow it is safe to believe that our future is well assured.

A feature of the address which is likely to draw forth discussion is the suggestion that unlimited combination may be permitted, and that it might be feasible to allow coal to be mined and sold by a single corporation under national supervision as in Germany. The temper of the American people is not such as to readily allow the introduction here of methods of government that chafe even in Germany, and the problems which such a suggestion give rise to are many and perplexing. In engineering problems we have data to guide our action; we can, as Ostwald says, prophesy. If we construct a dam in a gorge we know from experience what will result, we know how strong to make the dam, how to construct the canals and conduits, how much water to distribute to the different tracts; we can even prophesy with reasonable accuracy the total cost of the work and the probable yearly profit from the enterprise. But when, for example, the Supreme Court orders the dissolution of a great corporation which has enjoyed a monopoly of the production of a necessary commodity, or when it is proposed to combine into a single corporation all the producers of a useful metal, no one can prophesy as to the cost and results of these undertakings. No one knows, no one can know, what would have been the history of the development of the petroleum industry had it been left in the hands of numerous independent producers. The scientific way to find out would be to go back and make the experiment under otherwise identical conditions. Obviously this is impossible. We can not apply the scientific method as yet to industrial conditions, enthusiasts to the contrary notwithstanding. So in proposing sweeping industrial changes we can not prophesy, we can only guess. In the experience of the engineer, guessing is always risky and often dangerous.

Among the features of Mr. Holmes' argument that should meet with unqualified approval another must be mentioned. Not many years ago the elective system was introduced into college curricula with great acclaim. Now the experience of years shows that the undergraduate is not, after all, the best judge of his own needs, and means have been provided to afford him guidance and to prevent his too complete disregard of what the experience of others has gone to show. Only the naked savage can enjoy perfect liberty. With increase of civilization comes increasing restraint, necessary to secure the greatest good to the greatest number. It is natural that the individual should chafe at restraint; it is none the less necessary that he be placed under it. The recent statements by E. H. Gary before the Congressional Investigation Committee are of great interest in this connection. He emphasized the importance of protecting the people against imposition by great combinations of wealth, and stated his belief that enforced publicity and governmental control of corporations, even to the extent of governmental control of prices, is both necessary and desirable. An enlightened individualism will in the end secure the greatest aggregate good, but we must guard against an excess of individualism and a deficiency of enlightenment. The basis upon which Mr. Holmes founds his argument for a stricter observance of duty by individual, State, and Nation is a sure one, and the mining profession may confidently expect from the Bureau of Mines influence that is potent and achievement that is noteworthy in the development and use of our mineral wealth.

Individual, State, and National Rights in Mineral Resources

By J. A. Holmes

*The very abundance and cheapness of American resources has developed a habit of waste which is a great menace to our future welfare. The waste of the past and present, and the rapidly increasing needs of the present and immediate future, entail on us a still greater obligation to strive for the highest possible efficiency in the future mining and use of our mineral resources. All unscientific or inefficient use of resources is waste, and the most important factor in the movement for the rational conservation of our resources is the fact that the seemingly necessary waste of today may become the avoidable waste of tomorrow.

One of the facts which is to our national discredit in comparison with other countries is that the statistics of men employed in mining operations in the United States, show that the percentage killed in our mines is three times as great as that in most other mining countries. I am glad to be able to report that, whereas, during the three years from 1905 to 1908, the death rate in our mines increased not less than 30%, during the three years that followed this, the death rate has decreased nearly 30%. There is still great need of improvement. In our mines during the past ten years, more than 30,000 men have been killed, and more than 100,000 have been injured; and many of those injured have been maimed for life, through the lack of prompt and suitable treatment. But the movement for better conditions is under way. The operators and the miners are co-operating with the State inspectors and National Bureau of Mines in a determined effort to make American mines as safe as those in any other country. Miners in every part of the country are being instructed in the methods of preventing mine disasters, and of rescuing the injured, and of caring for the injured so they can be properly treated by the physicians. Government rescue cars with trained experts are traversing the mining camps in every part of the country, and every effort for the betterment of conditions that is being made by the Federal and State Governments is finding hearty response and co-operation on the part of the operators and miners.

Investigations into the causes of mining accidents by the Federal Government, the enactment of better mining laws among the several States, increasing activity on the part of State mining inspectors; best of all, greater safety precautions on the part of the operators and miners, and the development of a strong, earnest spirit of co-operation between the mine owner and the mine workers, all give promise of a serious, general effort to make mining in the United States safer and more creditable from a humanitarian as well as from a business standpoint.

Let us, therefore, consider briefly some of the rights and duties of the individual, the State, and the Nation in utilizing our mineral resources. In the past the individual has been the factor of incalculable value in the development of the world's resources. As an explorer he has discovered new countries; as a prospector he has discovered the new deposits of mineral wealth; as a miner he has developed these resources, and made them valuable for use in the industries and arts. And when the undertaking has proved too large for a single individual, he has associated with himself other individuals, and the corporation thus organized has carried the work forward.

In the aggregate, probably, for every dollar taken out of the ground by the explorer, the prospector, and the miner, a dollar or more than a dollar has been expended by them. Nevertheless, the lure of gold has led them forward as explorers, prospectors, and miners; and the hope of profit has carried them forward despite all discouragements and failures. Nor have the benefits resulting from their work been limited to mining operations. They have paved the way; they have been followed by the farmer and the manufacturer, and thus they have not only opened up, but they have developed countries and continents.

But if the individual has accomplished so much through his efforts, then why should the public today become dissatisfied with the arrangement and ask to have new laws enacted; new regulations adopted concerning the relations of the individual and the public. It is because the individual has been wasteful in his methods. He has claimed the right of supreme ownership of the mineral resources which he discovered, even though these resources may have required millions of years for their creation; they may be indispensable to the public welfare; they may be the only supply available for this purpose within reasonable reach; and the individual claimant has done nothing toward their creation or their inherent value; and his claim to ownership may be only that based on discovery or purchase for a paltry sum from some other person who made the discovery, and who was willing to dispose of his supposed birthright for a mess of pottage. He claims the right to mine those resources as he chooses, even if his methods involve enormous waste. He declines to recognize the claim of the public that the people are the supreme owners of these resources, and that the individual holds them in trust for development with profit to himself, but keeping the permanent welfare of the people steadily in view.

The life of the individual is admittedly short. His plans and ambitions relate to temporary purposes and present profits. Generations of individuals come and go; the State alone is perpetual; and the State must safeguard its own future. In the past the chief idea of the State has been, and naturally so, to encourage individual effort; and with this in view, it has explored and published reports on its material resources. Material development has always been and must continue to be, an important basis of the State's growth. This present development of resources is the motive that has generally led to the establishment of State geological surveys and State mining schools; and great good has resulted from the efforts of the State along these lines. The exploration of hidden or unknown resources in different parts of the State and their advertisement to the world through publications and geological reports has brought in new capital and additional settlers; has led to a wise use of home capital and labor, and has otherwise brought growth and prosperity to the State. However, this is usually related to the present development, without special reference to the future.

In carrying out its new purpose and new duty, the State must not only encourage present development, but must safeguard its future progress. This does not mean that the State should check development by endeavoring to save for the future what the citizens of today need for their own use. It means that the citizen of today, in the use of this material, while he has the right to use what he needs, has no right to waste or misuse that which he does not now need, but which his children and his children's children will need hereafter. He has neither created nor can he add to these resources, nor can he replace them by others when the present supply has been exhausted. He can and should, therefore, mine, prepare, and use these resources with the least possible waste, and with the greatest possible efficiency. It is the duty of the State to see that this is done.

And the State has a right to safeguard its own future, or, as the Supreme Court of the United States has recently expressed it, "The State as guardian of the public welfare possesses the constitutional right to insist that its natural advantages shall remain unimpaired by its citizens." In the developing and carrying out of this purpose, it is necessary and proper that the State should employ its own engineers, chemists, and geologists; that it should establish and support its own mining schools, with a view to training its citizens how to mine and utilize resources with greatest efficiency and least waste.

*Portion of Commencement address, Missouri School of Mines, May 26.

The geologist and the engineer in the employ of private capital must primarily regard present profit. Any other policy on his part has usually resulted in his seeking other employment. But the geologist and engineer in the employ of the State must give primary consideration to the public welfare, and the public welfare requires that, while in the development and use of material resources present profit cannot be neglected and must not be made impossible, a way must be found of using these essential resources with minimum waste; in order that, while not preventing profit today, the resources not needed today may be saved for the needs of tomorrow. The needs of neither the individual, the State, nor the Nation will be curtailed; on the other hand, these needs will in the future increase with the extent and the variety of our industries; they will increase even more rapidly than our population.

Furthermore, the present generation has both the power and the right to use these resources, in so far as it will use them efficiently. It has the right to use as much of these resources as it actually needs, but in each State, as in each country, there is but the one supply of mineral resources, and when this one supply is gone, there is no other supply to take its place, except the supply that may be brought in from other countries and for which due tribute must be paid. Whether we consider the resources of a great State like Missouri, or of the United States as a whole, there can be no doubt as to the fact that, measured in terms of the life of the State, or of the Nation, we shall, while the State and the Nation are yet in their infancy, exhaust the existing supply of these resources, unless we use them in the future less wastefully than we have been doing in the past.

At the same time, we may as well understand that the individuals of this generation will not mine, extract, or use mineral resources in such a manner as to entail financial loss on themselves in order that the supply may be left for the use of future generations. There will be no mineral industries without profit to those who engage in them. Any consideration of the doctrine of conservation of resources for the benefit of future generations must give equal consideration to the doctrine of reasonable compensation for those who have capital to invest. Investors are entitled to a reasonable return on their capital, and a man who has labor to invest is entitled to profit from it; but neither private gain nor public greed should be allowed to destroy a nation's liberty, or those resources essential to a nation's life. In considering the rights and the duties of the Nation in the development and use of its mineral resources, we need not, at this time, discuss the constitutional relations between the States and the Federal Government. I grew up in a State where the men spent much of their time discussing the relative rights of the States and the Federal Government. It is high time to give more thought to questions of duty, rather than questions of rights. The great purpose which we should now keep in view is that of the permanent welfare of the people of this country. Constitutions are made by and for the people, not the people for the constitution. "What are constitutions, anyhow, among friends?"

For convenience in administrative affairs, our forefathers, in framing the constitution, assigned certain local duties and rights to the several States, and to the Federal Government certain other duties and rights pertaining to interstate, national, and international functions. The police supervision of mining and metallurgical operations undoubtedly comes within the province and function of the State; but the products of the mine make up more than half the interstate commerce of the country; they now constitute a large, and will hereafter constitute a much larger, part of our international commerce; and neither the interstate nor the international commerce can be carried on without them. They are inseparably associated with the general welfare—whatever that means—of all the people. The coal and other raw products of certain States are essential factors to the convenience and comfort of the people in many other States. They are also essential to the manufacturing enterprises in all the States. The phosphates produced in three States are essential elements in fertilizers, now considered necessary for crops in all parts of the country. The coal and the steel from certain States are indispensable factors in the transportation of our mails and in the movement of our army and navy, and other national functions.

The Federal Government, therefore, has both its rights and duties to perform; and the important question is not how we can avoid the conflict of rights between the Federal and State governments, but how each can do its duty in behalf of the wise development of mineral resources, and this without delay or unnecessary duplication of effort. Whatever may be said of the duties of the Federal Government in behalf of agricultural industries, may be said with equal and even greater force concerning its duties and its efforts in behalf of mining industries. In agriculture we have, recurring crops coming with the returning seasons. Of our mineral resources we have but this one supply.

There are many needed inquiries and investigations which, if conducted by each of the several States, would lead to large, unnecessary duplication in cost and effort. These may be conducted by the Federal Government for the benefit of the people in all the States. There is a large amount of educational work which the Federal Government should do in behalf of the mining industry along lines similar to educational efforts in behalf of agriculture. At every point where the mining industry touches the interstate and international commerce, the guiding and helpful hand of the general Government should be applied. National and State governments should co-operate to help the individual in the proper development of mineral resources and should be careful not to hinder his efforts, except when these efforts are not in accord with best public interests.

From time to time it has happened that drastic State legislation has for the time being seriously crippled—and unnecessarily so—certain branches of industry; and today the proper development of mining industries is hampered in many respects because of the lack of uniformity in legislation in the different States. Furthermore, both State and National legislation may retard the proper development of mining by preventing the needed co-operation among individuals with a view to reasonable increase in the price of mineral products—an increase in price necessary to the introduction of such mining methods as will safeguard the lives of the miners and prevent the waste of essential resources. In all these efforts for the betterment of the mining industry, there should be hearty co-operation between the Federal Government dealing with the broad general problems of value to the entire country, the States dealing with problems more or less local to themselves, and the private corporations dealing with still more local or individual problems. Thus we shall have greatest efficiency, and largest results, at least cost.

I see no objection to any combinations of persons or capital or holdings or mineral properties for operative purposes. Experience and reason both indicate that such combinations may make for stability of business, for economy and efficiency in production, for lessening the loss of life, and lessening the waste of resources. I even commend for earnest consideration in this country the German system by which nearly all of the coal produced in that country is sold under a single syndicate dealing direct with the purchaser and consumer, without the aid (and without the added cost) of the middle-man and his advertising agencies, this coal being sold at uniform prices which are reasonable and fair alike to the producer and the consumer, and furnish reasonable safeguards of the public interests as to the saving of life and prevention of waste. In the future mining and preparation for use of important American resources, it is not so much these questions of combinations of capital about which we need concern ourselves, as it is that of ultimate control. We must see that the people of this country exercise their supreme right and duty in requiring that these resources be utilized in such manner as will best promote the permanent welfare of the citizenship of this Nation.

Operation of the Goldfield Consolidated Mill

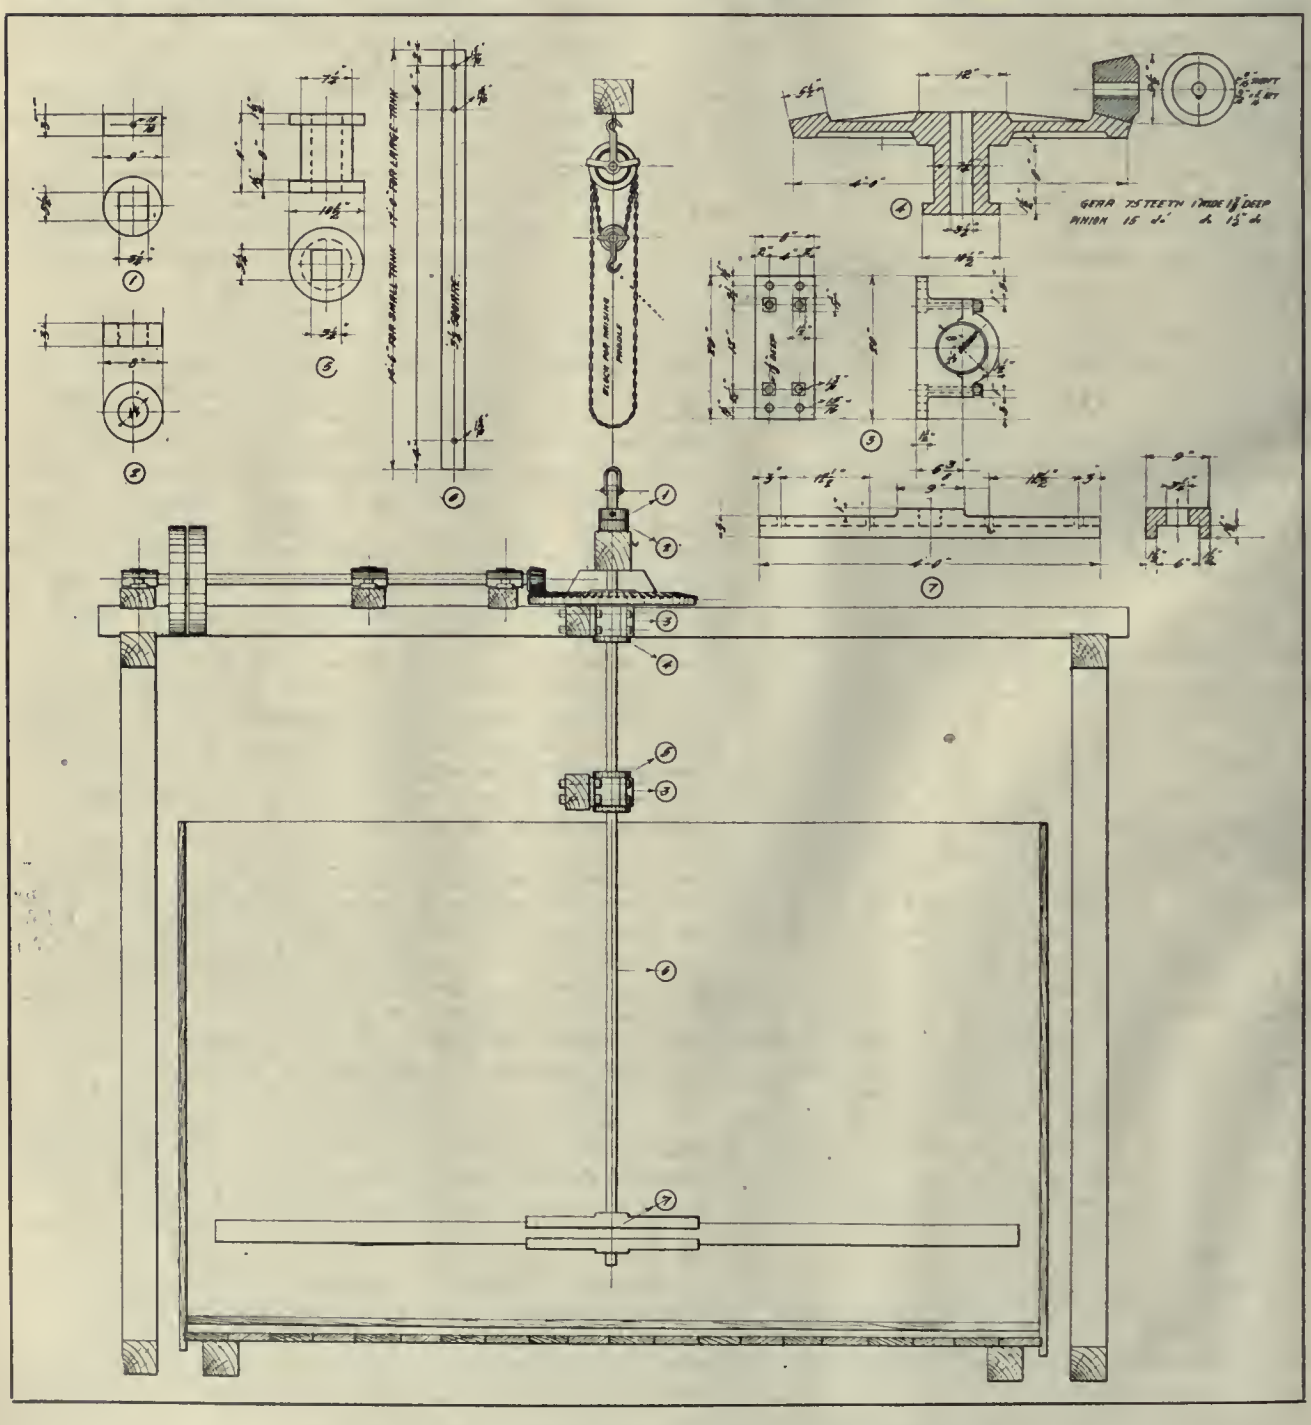
By J. W. Hutchinson

(Concluded from page 719.)

Concentrate Treatment.

Up to June 1908 very little progress had been made in evolving a process for treating the high-grade concentrate which would be produced at the mill. This product from the Combination mill of this company had been shipped to the smelters until J. H. Mackenzie assumed the management. The freight and treatment charges were so excessively high at that time that he decided to store the concentrate, pending the solution of the problem of treating it. The reports to the management by the former metallurgists of this company stated that roasting would be necessary for economical treatment, although the results of the tests made did not prove conclusively that the concentrate could be treated successfully in this way.

As can be seen from the flow-sheet on p. 686, concentration follows tube-milling. Roasting the –200-mesh concentrate, containing 30% sulphur and 20 oz. gold, to put it mildly, seems dangerous. In addition, roasting is not necessary. Much of the visible gold in the ore from this company's mines, although apparently free, is so coated that it cannot be recovered by amalgamation, and is only slowly soluble in cyanide solution. During the summer of 1908, when engaged in experimental work on the concentrate, an acid wash was applied for the purpose of removing this coating, in order to amalgamate the coarse gold if possible. It was found that this acid wash did remove the coating, and that much more gold could be recovered by amalgamating the concentrate after an acid wash had been applied. It seemed probable from this result that cyanidation of the raw concentrate would be facilitated by the same process, since it was not reasonable to suppose that only the coarser particles of gold were thus coated. Experiments were made on a laboratory scale and the results were astonishing. Approximately 90% of the gold in 20-oz. concentrate was dissolved in 8 hr. contact with a 4-lb. solution of cyanide, after a preliminary acid wash. The results were corroborated by larger tests, and were so encouraging.



ADJUSTABLE GEAR AND PINION AGITATOR, GOLDFIELD CONSOLIDATED.

the management leased the old Kinkead mill for the purpose of treating the accumulation of concentrate from the Combination mill. During the summer of 1908 approximately 300 tons was treated and yielded 94% of the gold content, at a cost which made it seem advisable to build a plant of similar type at the 100-stamp mill. It was found during experimental work, that the solutions became inert after 8 hr. contact, and that it would be necessary to remove them and re-treat the concentrate with a solution freshly precipitated and freed of reducing agents. As originally designed and operated, the process of cyanide treatment after the acid wash consisted in agitating for 8-hr. periods in Pachuca vats, passing the pulp at the end of these periods through Dorr continuous thickeners; the clear overflow passing to the precipitating department and the thickened pulp to a second Pachuca vat, where a regenerated solution was added. This arrangement proved expensive, since it necessitated pumping the concentrate each time, and was abandoned. The process in use now consists in agitating the concentrate for 8-hr. periods, and settling and decanting in the Pachucas, and is very satisfactory. During the first year's run, much difficulty was experienced in evolving a mechanical stirrer for the pulp during the acid wash and the subsequent water washes. The sketch on the preceding page gives the details of the present arrangement, which is very successful.

The concentrate from the mill gravitates through wooden launders to four 48 in. by 16 ft. amalgamating tables. The last section of these tables is covered with carpet for removing the coarser particles of gold, which do not amalgamate. The recovery by the combined process of amalgamating and carpeting amounts to approximately 35% of the value of the concentrate, or 25% of the value of the ore. Of this amount, 10% is contained in the carpet concentrate, which is briquetted with the precipitate from the cyanide plant, and supplies the necessary sulphur for matting the copper in it. The pulp from the plates runs to three 10 by 20-ft. redwood collecting and agitating vats, fitted with the above-described adjustable stirrer. When a charge is being collected, the vertical shaft is pulled up by means of the chain-block, so that there is no difficulty in starting it up. Each vat holds one day's run, amounting at present to 50 tons of dry concentrate. After the charge has been collected, the water is decanted, leaving a pulp containing approximately 50% moisture. The agitator is started up and gradually lowered until the whole charge is in motion. To this is added 66°B. sulphuric acid in the proportion of 20 lb. per ton of concentrate, and agitation continued for 8 hours. The vat is then filled with water, after which the agitator is shut off and raised, and the charge allowed to settle. The clear solution is decanted and runs to a special tank in the mill, is neutralized there, and used in the mill for crushing purposes. Two more water washes are added in like manner, equivalent to 6 parts by weight of water per ton of dry concentrate. The last water wash is decanted as closely as possible to avoid subsequent dilution of the cyanide solution, lime added in quantities to raise the alkalinity to ½ lb. in terms of CaO, the agitator started, and when the charge is in motion, 1 lb. of lead acetate per ton of concentrate is dissolved in water and added to the pulp, which is kept in motion until time to pump to the Pachucas.

It has been found most necessary here not to let the concentrate be in contact for any length of time with a weak solution of cyanide. For this reason the amount of cyanide required to bring the solution on the charge to 4.5 lb. KCN per ton, is first dissolved in the Pachuca agitator and the charge pumped into this. Exactly what effect a dilute solution of cyanide has on a heavy sulphide ore is not known here, but that the effect is deleterious has been demonstrated beyond question by the following results. In order to avoid the small mechanical loss of cyanide due to neutralizing the concentrate with milk of lime, it was decided to slack the lime with solution from the mill. This

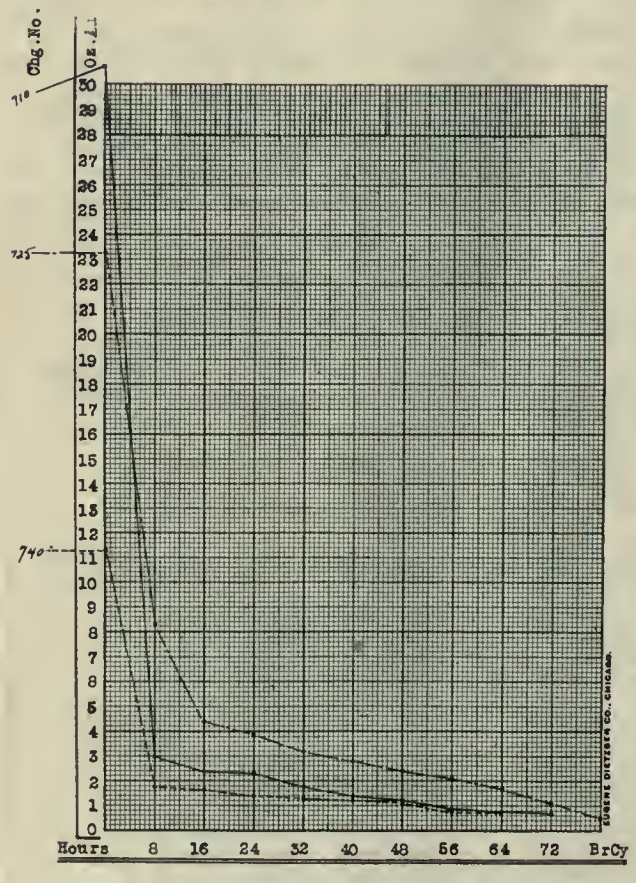
was done, and titration of the solution in the neutralizing tank showed a content of from 0.2 to 0.3 lb. KCN per ton. This practice was continued for nearly two weeks, with the result that the assay value in the tailing was doubled. Immediately on discontinuing the KCN solution in the neutralizing tank, the extraction came up to normal. This has been tried on different charges since, with the same result each time.

The same effects have been noted when treating a heavy silver sulphide ore which had been crushed in water, and then transferred to the strong solution in the agitators. When this same ore was crushed in the mill solution, and allowed to stand in the dewatering tanks in dilute cyanide solution, before being transferred to the agitators, the extraction was materially reduced and the strength of the solution used for agitating had to be increased in order to approximate the same results obtained by cyanidation after crushing in water. It is not to be understood that crushing silver sulphide in water is believed to be the most economical plan for low-grade ores, but the instance is cited to show that contact with a weak solution of cyanide is deleterious to the treatment of concentrate and ores containing large quantities of sulphides. At the end of the fourth hour, in alternate periods, peroxide of sodium is added to the charge, which increases the activity of the solution and reduces the time of treatment. One-tenth pound lead acetate per ton of dry concentrate is added to each solution at the beginning of the period.

The accompanying chart, showing the extraction graphically by periods, is representative of the various conditions



EXTRACTION CHART, GOLDFIELD CONSOLIDATED.

and grades of concentrate. For two years the extraction of gold from the pulp in the Pachuca agitators has averaged 93%, and the total extraction by amalgamating, carpeting, and cyaniding has averaged 95.23 per cent.

A Kelly filter-press (type B) containing 400 sq. ft. of filter surface is used for filtering the concentrate. It was found necessary to set this machine at a much greater inclination than is required for ordinary slime, since the heavy pulp has a tendency to pack in the bottom of the cylinder, which prevents the carriage from running out freely. The labor of one operator and two trammers is required to filter and dispose of 50 tons of concentrate in 8 hours. On this material the capacity of the Kelly press is equivalent to 750 lb. concentrate and 1200 lb. solution per square foot of filter per day of 24 hours.

The cost of cyaniding the concentrate is as follows:

Labor	$0.93
Supplies	4.44
Power	0.48
Total	$5.85

On the preceding page is given a chart of the power-load analysis by tonnage which is sufficiently self-explanatory. This is the chart mentioned upon page 617, where the cost of the average power load, 1.73 hp. per ton milled, is given as 32c. per ton.

A RED AND WHITE SOLUTION for writing on blue-prints may be made by a crystal of potassium oxalate, about the size of a pea, in an ink-bottle full of water. This solution will give white lines on blue-prints; other potash solutions are yellowish. If this shows a tendency to run, owing to its too great strength, add more water and thicken slightly with mucilage. Mix this with red or any other colored ink, about half and half, and writing may be done on blue-prints, in colors corresponding to the inks used.

Amalgamation on the Rand

By W. R. Dowling

*It is found that the present increased use of tube-mills for re-crushing enables so coarse a screen to be used in the stamp-mill that amalgamation of battery pulp becomes an impossibility owing to the scouring action of the coarse pulp upon the mill-plates. This necessarily leads to the removal of the plates from the stamp-mill in such cases, and a consideration of the following possible alternatives represented graphically in the corresponding diagrams:

A. Amalgamation of the tube-mill pulp by one set of plates, and the overflow final pulp by another set, as at the Randfontein Central and Knight Central.

B. Amalgamation of the tube-mill pulp only, as at the Simmer & Jack, Simmer Deep-Jupiter, and the various South Randfontein mills.

C. Amalgamation of the mixed pulp after re-grinding of the coarse portion by tube-mills, as at recently erected plants.

After the failure of various efforts to eliminate tube-mill plates, it may now be accepted that there is general agreement among metallurgists as to the advisability of amalgamating the tube-mill pulp, since otherwise considerable concentration of coarse gold by the classification of both stamp and tube-mill pulp takes place in the tube-mill circuit. Tube-mill pulp has only to be examined for metallic iron from the wear of shoes and dies and from other sources to illustrate how heavy particles will persist in the circuit till crushed or abraded fine enough to overflow the classifiers.

With efficient tube-mill classification, all but the finest gold released by the stamps is brought into the tube-mill circuit and recovered on the plates, together with that released by crushing in the tube-mills. This being the case, the problem narrows itself down to determining whether it is necessary or advisable to amalgamate the final pulp, leaving the crushing plant as an overflow of the tube-mill classifiers. The considerations which enter into this problem are the extra capital outlay and buildings, the capital locked up as amalgam as setting to the plates, the increased area of amalgamated surface to guard, the consumption of mercury, the labor of dressing, and the additional elevation of pulp necessitated by its fall during this amalgamation process. Even if mercury traps are used at the foot of amalgamated plates outside the tube-mill circuit for the pulp overflowing the tube-mill classifiers, it is possible for fairly coarse mercury and amalgam to escape to the cyanide plant.

On reference to the sketches, it will be noted that alternatives A and C have two elevations of the total pulp, plus the tube-mill pulp, whereas B has only one elevation of the total pulp, plus the tube-mill pulp. Alternative B therefore does not involve any extra charge for re-elevation, and remains the same as in the usual present-day practice, as represented in sketch D. Unless increased recovery counterbalances these disadvantages, it is preferable to omit this additional operation. The use of very coarse battery screening naturally reduces the amount of metallic gold set free in the stamp-mill, and where the bulk of the crushing is done by the tube-mills, the quantity of very fine gold which might reach and overflow the tube-mill cones is correspondingly reduced, as such gold is retained on the tube-mill plates before the elevation of the tube-mill pulp. Even where the coarseness of crushing in the stamp-mill does not preclude the use of plates there, their elimination, when conditions permit, is followed by the various advantages above mentioned, and the rendering available as immediate profit the gold on the plates, which would otherwise not be realized until the end of the life of the mine. Plates thus taken out of the stamp-mill may carry from £50 to £300 worth of gold per plate, according to their condition, and in the aggregate this may render some £20,000 worth of gold immediately available in the case of a large mill. The elimination of the final pulp plates, however, can only be considered safe where good tube-mill classification obtains, and an equally efficient cyanide treatment follows. In the cyanide plant clean separation of sand from slime is essential, such as is possible with large diaphragm cones and continuous sand collection, producing on the one hand freely leachable sand, and on the other a large percentage of slime free from coarse sand. With tube-mill classifiers liable to choking of small underflow outlets and consequent overflow of coarse sand and gold to the cyanide plant, and with slimy semi-permeable sand charges, the wisdom of allowing any fine amalgamable gold to escape from the crushing plant is doubtful, in spite of the economies above mentioned. In the case of the Simmer & Jack mill, where there are plates in the tube-mill circuit only, though the cyanide residue remains normal, the amalgam recovery dropped from 64 to 55% on a 6¾-dwt. ore, owing to the fact that the fine sand and slime overflowing the classifiers is not amalgamated at all. If necessary, and as shown later in the case of the Simmer Deep plant, finer crushing and larger relative tube-mill cone area could be employed to increase the percentage of gold recovery by amalgamation. While the collected sand is slightly enriched by some very fine free gold, there is no difficulty in dissolving this and obtain-

*Abstract from the *Journal* of the Chemical, Metallurgical, and Mining Society of South Africa.

ing a complete recovery. The popular theory that only 85% of this gold is recovered by cyaniding, instead of 100% by amalgamation, has not so far been borne out either in the laboratory by residue assays or regular panning of residues. Any fine metallic gold overflowing the tube-mill cones is necessarily smaller and more easily dissolved than the average of partly-encased particles in sand which are dissolved by cyanide. The amount of fine metallic gold overflowing the tube-mill cones is much affected by the number and area of the latter. Where a large ratio of tube-mills to stamps exists, such gold, more often than not, can not be detected in the final pulp by panning, or in the sand before treatment. This is the case at the Simmer Deep plant, where, before the removal of the stamp-mill plates, the total plates in operation numbered 82, equivalent to 5276 sq. ft., of amalgamating area, and the amalgamation recovery was 56.8% of the ore value. After the removal of all the stamp-mill plates and the reduction of those in the tube-mill circuit to 30 stationary plates, presenting an area of 1700 sq. ft., the amalgamation recovery was 57.7%, and the value of sand and slime before and after treatment has not increased. The total extraction by amalgamation and cyaniding was 93.4% before and 93.5% after removal of the stamp-mill plates. There was slightly finer crushing of the ore in the latter case, there being 77.6% of −90 mesh (0.006 in.) product in the final pulp before removal of the mill-plates, and 81.0% of −90 mesh (0.006 in.) product after the removal. Where the ratio is lower, as at the Simmer & Jack, a trace of very fine gold can be detected by panning the final pulp and collected sand, though the assay value of the sand residue remains normal. The slime is also enriched, though this may be offset by better washing, due to the lower percentage of moisture on settlement of well-classified slime, containing a higher percentage of fine (−200 mesh) sand. For instance, assuming that 1.5 and 1.8-dwt. slimes are treated, settling to 42.5 and 35% moisture respectively, by two 4 : 1 washes in both cases, of which the first wash only is precipitated down to 0.01 dwt. per ton of solution. With 0.08 dwt. undissolved gold in the first residue and 0.10 dwt. in the second, the total extraction will be 90.4% (0.114 dwt. total residue) from the 1.5-dwt. slime, and 92.2% (0.14 dwt. total residue) from the 1.8-dwt. slime. Where Butters or other vacuum filters are used, the value of the original slime should be immaterial, as, providing the dissolving of the gold is satisfactory, the residue should contain little more than the trivial amount encased. It is to be hoped that detailed results and working costs of the recent work in this direction at the Crown Mines will before long be laid before our Society.

The author is indebted to F. A. G. Maxwell for much information on regular work at the Randfontein Mines, where plates are eliminated from the stamp-mill, and hopes that he will bring forward his results as a discussion to this paper. In the meantime, it may be said that during 1908, in the four 100-stamp sections of South Randfontein, when there were amalgamated plates both in the stamp-mill and the tube-mill circuit, the average amalgamation recovery was 54.46%, and the total recovery 92.06%, whereas in 1910, when there were plates in the tube-mill circuit only, the amalgamation recovery was 48.60% and the total recovery 92.94 per cent.

As mentioned in a note lately presented by the author to this Society, it has generally been considered necessary for the satisfactory amalgamation of the large volumes of thick tube-mill pulp that the plates should shake. Tracing back the history of this belief to the pioneer work done by J. R. Williams on the Glen Deep in 1904, it seems that in order to prevent the banking of sand on the stationary plates installed with 10% grade, it was found necessary to mount the plates on shaking vanner frames. Not only has the shake been subsequently adopted by all the mines without question, but the number of plates has gradually increased from the two originally installed to five and even six later. When the Knights Deep had five tube-mills, equivalent in cubic capacity of shell to 3.91 standard tube-mills of 22 by 5½ ft., sixteen shaking plates 10½ by 4¾ ft. were in operation. As there was no convenient space for more plates when another tube-mill was erected, it was decided to make the sixteen plates serve. The number has now been reduced to fourteen. The ratios are:

For 3.91 tube-mills 16 plates = 4.09 plates per tube-mill.
For 4.91 tube-mills 16 plates = 3.26 plates per tube-mill.
For 4.91 tube-mills 14 plates = 2.55 plates per tube-mill.

The amalgamation recovery was just as efficient with the smaller ratio as with the larger.

A TYPICAL SCENE ON THE RAND.

In the course of the experiment mentioned in my note, and after having thoroughly tested the stationary five-plate system, initiated originally by F. A. G. Maxwell at Randfontein, it was decided, on W. A. Caldecott's suggestion, to perform the whole amalgamation of the tube-mill pulp on two stationary plates per tube-mill. The Simmer East plant has three 22 by 5½ ft. tube-mills. The pulp of each mill has been regularly run over two plates only since December 19, 1910. The dressings have been at six-hour intervals and the scrape taken 6 in. lower than formerly. The daily scrapes have been normal, yielding the amalgam called for. The two plates of one of the mills were steamed at the beginning of the run and again at the end of the month's run to determine whether the yield from this source was affected in any way. The previous practice in this plant was to steam one-third of the total plates each month, so that each plate ran for three months before steaming. It was found that one month's run of the two plates yielded more amalgam when multiplied by three, than the average of the three months of five shaking plates previous to starting the non-shaking experiments. However, to be on the safe side, it was assumed that the plates would not accumulate steam amalgam at the same rate during the second and third months, and it was decided to multiply by only two and a half. This calculation gave a figure for steam amalgam just about equal to the average of the three months of five shaking plates. Adding this to the daily scrape and other sources the recovery is fairly arrived at, and works out at 21.54% of the screen value and 34.17% of the tailing value, compared with 21.80 and 34.04% of the previous five-shaking-plate period.

To ensure successful and economical work the ratio of water to solid should be reduced to a minimum, as not only does this decrease the velocity of the stream over the plate, but the cost for re-elevation is also less. The volume of pulp of 400 tons of sand per tube-mill plus 480 tons of water, allows about 10,000 cu. ft. of pulp per 24 hours for each of the two plates, or about the same as passes over the plate of a 5-stamp battery with a 9-ton duty per stamp, and a 6.5 to 1 ratio of water to ore in the screen pulp. The tube-mill circuit is the only part of the crushing plant where a thick amalgamable pulp is available without the installation and operation of special classifiers for the purpose. Distribution of the stream across the full width of the plate is also of considerable importance, and may be obtained by using the usual box at the head of the plate perforated with about ¾-in. holes along the bottom of the side facing down the plate. These holes should be of such capacity that the pulp attains some head in the box. In the event of any of the holes becoming temporarily choked, a further row of holes an inch or two higher up the front side of the box will serve to carry over the stream, and still maintain a fairly good distribution. The fall given to the stationary plates is 18%. This is the fall arrived at by Mr. Maxwell and since adopted here. With a fall of 18% it is found that the minimum percentage of water in the sand is 55%, and it appears that should it be desired to reduce the fall, the moisture would have to be increased, fall and water ratio being convertible terms within limits. The point to be reached in water ratio and fall is that just short of banking of the sand on the plate. Even with a low water ratio the rush of pulp over two plates appears to the eye to be too great, but this is not really so. As long as the velocity of the pulp stream is such that particles in suspension may come into contact with the plate and not be carried on mechanically without touching the plate, the gold will be caught. It might be considered that pulp carrying only 55% of moisture is too thick to allow the gold to sink through and reach the plate. As, however, amalgamation has been proved efficient with this ratio, it would not appear to be the case. In this connection, it might be mentioned that in pan amalgamation the pulp is kept very thick, although in plate amalgamation a fluid pulp was heretofore considered necessary for good recovery. On a stationary plate there is a tendency for the gold to amalgamate farther down the plate than when shaking; there is hence a liability for the scraping to yield less amalgam and the steaming more with stationary plates as compared with shaking plates. In connection with the satisfactory results obtained in the operation of the two-stationary plate method, much credit is due to the practical skill and progressive attitude of A. J. Herald, the Knights Deep mill foreman, and to his assistant, Peter Wilson.

The removal of plates from the stamp-mill has had the good result of introducing on these fields the separate plate-house. The Homestake mine and the Waihi set the example many years ago, but the Witswatersrand has been very slow in following the lead and accepting the suggestion made before this Society in 1903 by H. R. S. Wilkes. The arguments advanced by some mill-men that a plate attached to each battery makes for good recovery due to better distribution of the pulp by the stamps over the width of the plate, and that even vibration assists, lack confirmation. It appears to me that this method is just one of the many practices taken over from other countries without investigation. Tube-mill plates have now been running long enough to prove that most efficient amalgamation can be performed with a pulp sub-divided from a launder and distributed over the width of the plate from a box pierced with holes. Tube-mill pulp carries heavier particels and contains less water than other mill pulp, and is therefore a more difficult pulp to distribute. The advantages of a separate plate-house are increased running time, since stamps need not be stopped for plate dressing, and greater attention to the crushing machinery by the attendants, thus increasing the crushing capacity. Again, better amalgamation should be obtained by the greater attention to the work by specially chosen and trained men. The whole operation is confined to a smaller area and lends itself to closer supervision so that the risk of loss by pilfering may be reduced to a minimum.

In connection with the matter of the method of conveying pulp the author considers that sufficient importance is not attached to launders. All launders should be as smooth as possible and free from obstruction at the joints. Of all material used for the lining of launders there does not seem to be anything better than cement. This provides an ideal surface presenting least resistance to the flow of the pulp and affording very little lodgment for amalgam and still less for gold in unamalgamated pulp. On those mines here, where separate plate-houses or combined plate and cyanide extractor houses have been built, the arrangements have not gone far enough or else too far. The erection of zinc-lathes, elevator pumps, and tube-mills in the same building with the plates and the extractor boxes means the introduction of gangs of men and natives for repairs, other than those engaged on the gold recovery work. If this machinery is placed in the same building because the launders may carry gold, then the whole tube-mill plant, including circuit launders and elevators, should be included. The best plan is to include in the building only such machinery as is actually connected with recovery work, so as to limit the men entering the building to those directly engaged in the work. The accumulation of amalgam in the tube-mill launders should be reduced to a minimum and the launders should be closed to protect what does collect. Prior to the introduction of tube-milling, amalgam was to be found in the launders to the cyanide plant, and some found its way as coarse particles to the concentrate vats, entailing loss in the residue. Where efficient tube-mill classifiers are installed no amalgam is found today reaching the cyanide plant except in an impalpably fine condition, since heavy particles of amalgam pass into and are retained in the tube-mill circuit. There is always a loss of mercury in amalgamation mainly by abrasion, and where this enters the tube-mill, amalgamation of the gold liberated by crushing takes place. Where this amalgam does not reach the plates it is found in the launders between the discharge of the tube-mills and the plates. Such impalpably fine mercury or amalgam as enters the cyanide plant dissolves in the same way as gold, and, like dissolved lead salts, is either wholly or partly precipitated by soluble

sulphides in the working solution, or later in the metallic form by zinc shavings in the boxes.

Where plates are eliminated from the stamp-mill the water ratio may be considerably reduced. The clearing of a long plate, set at a fall of 9 or 10% by avoidance of any banking of sand from the pulp, has been the factor determining the water ratio in the past, and this requires six to seven parts by weight of water to one of solid using average battery screening. It has been found that in the absence of mill plates the ratio may be reduced to 4½ without serious ill effects provided the mill launders have sufficient grade to carry pulp of this consistence. A coarse screen with less water will give the same result in duty and grading as a finer screen and more water, water and screening being convertible terms within limits. The reduction of water has considerable influence on the cost of pulp elevation and of running water pumps, the reduction of weight from 6.5 to 4.5 of water to 1 of solid being equivalent to about 27%. The saving in power in a large plant is material when working on the reduced ratio, and there is likewise a smaller load on the classifiers and slime collectors. There would, however, be no saving in the consumption of water, as much the same volume is exposed to loss by evaporation, seepage in dams, and moisture in residue.

Although there is no rule for the area of amalgamating plates there is no doubt that the number and area of plates in common use is unnecessarily large and when these are placed in a separate plate-house the total area may be materially reduced. The author is of the opinion that much

TURF SHAFT, JOHANNESBURG.

of the amalgam found at the lower end of long battery plates is largely worked down by amalgamators wishing to present a uniform bright surface all over the plate. The old practice was to use plates about 15 ft. long by 5 ft. wide per battery of 5 stamps, which equals 15 sq. ft. per stamp. Where, say, one standard large tube-mill for 30 stamps is erected, and assuming that the tube-mill is equivalent to 30 stamps, five plates of 11 by 5 ft. would probably be used. The combined plate area is then:

30 stamps = 6 plates 15 × 5 ft. = 450 sq. ft. = 15 sq. ft. per stamp.

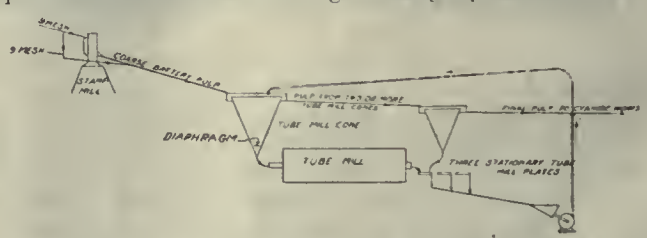
1 tube-mill = 30 stamps : 5 plates 11 × 5 ft. = 275 sq. ft. = 9 sq. ft. per stamp.

Total for 60 stamp units = 725 sq. ft. = 12 sq. ft. per stamp unit.

At the Randfontein Central the total plates erected amount to 9.6 sq. ft. per stamp unit, but it is now proposed to use only 4.8 sq. ft. per stamp unit, and there is little doubt that the latter area will be quite sufficient. In the Simmer & Jack re-arrangement the plate area is about 2 sq. ft. per stamp unit. With the high stamp duties of recent years the same plate area is doing nearly double the work it used to do in the past, and is capable of doing a great deal more. Conversely, in regard to the usual 10% fall, where this is increased more crushed material with smaller water ratio may be amalgamated with equally good results. H. W. MacFarren, in his interesting little book, says the fall of plates varies from 1½ to 3 in. per foot, and should not be less than 2 or 2½ in. A fall of 2 in. per foot is equivalent to 16.7%, and 2½ in. to 20.8%, while the average is 17.75%. Among the advantages due to reduced area of plates are reduced cost of installation and operation, and especially a reduced cost of mercury; the consumption being in proportion to the area of plate. In the Simmer & Jack plant the consumption of mercury has been reduced to one-sixth of the former figure. Where a large area is exposed in amalgamation a proportionate amount of gold is taken up to set the plates, and is not available for realization until the end of the life of the mine. The gold held by well-set plates may be taken at 1 oz. per sq. ft. of plate. A 200-stamp mill having 40 plates 15 by 5 ft. will thus absorb 3000 oz. of gold, worth £12,000. The future indicates a reduction of plate area to the point

TUBE-MILLS AND SLIME PLANT, SIMMER DEEP.

where only the gold too coarse for cyaniding will be caught by amalgamation. This has probably been reached already in the Simmer & Jack plant, which has now only 18 stationary plates in the tube-mill circuit in place of the former 64 battery plates and 30 shaking tube-mill plates. It will be noted that the Simmer East with plates in the stamp-mill has retained two stationary plates per tube-mill, whereas the Simmer & Jack and the Simmer Deep-Jupiter joint plants without plates in the stamp-mill have each retained three plates per tube-mill. The additional plate in the last two cases is a measure of safety to deal with the richer pulp and to have not less than two plates per tube-mill in action during dressing operations. Dia-



E. PROPOSED ARRANGEMENT, THREE STATIONARY TUBE-MILL PLATES.

gram E shows a proposed arrangement of crushing and amalgamating and three stationary plates per tube-mill and no plates in the stamp-mill, and with safety cones for the common streams of pulp overflowing the tube-mill classifiers.

In the manufacture of coke during 1909, more than $50,000,000 worth of by-products in the form of ammonium sulphate, creosote, pitch, and other materials were allowed to escape into the atmosphere, to do harm rather than good. The total value of the mineral products of the United States during the past year approximated $2,000,000,000. The products which were lost in either the mining or the treatment of these materials must have aggregated more than one-fourth of that, or in value more than $500,000,000.

Steamboat Mountain, B. C.

STAFF CORRESPONDENCE

Steamboat mountain is 35 miles southeast of Hope, near the headwaters of Skagit river. The international boundary is 45 mi. south of Hope, and prospecting has been extended over the surrounding district; good ore has been found from 23 miles from Hope, to the boundary and in United States territory. Some of the best discoveries have been made on Lightning creek, which follows the boundary. There is much activity in the camp and the surface indications are good, but a final estimate of the work of the camp can not be made until later in the summer when the returns for the season's work are in.

Dan Greenwalt made the first location on June 30, 1910, from Hope, but easy entry is obtained from Princeton on the east side.

At Steamboat two companies have townsites, and it is a question as to which one will get the population. Both are convenient to the locations in the district. Claims have been staked in all parts of the district, about 1000 in all. The discovery claim was at an elevation of 5400 ft., and many others are at an equal altitude on neighboring mountains. The ore generally is gold-bearing, with an average value of $15 to $30, but ten miles from Steamboat, toward Hope, a fine vein of galena has been uncovered by Frank Fritz.

Samples were brought to Vancouver two weeks ago by reputable mining men and the returns from these were extremely satisfactory. From 18 in. of the vein on the property of the Steamboat Prospecting Co. the ore ran $60; another 5 ft. went $2.80, while another sample was $537.

and brought the news into Vancouver. Interest was immediately taken in the district, and many locations were made during the autumn and winter. Many of these were on the snow, and warning was given by experienced mining men to be on the lookout for those who were offering these snow locations, in many instances made over other locations, for sale at $100 each. In Vancouver one man was offered ten of these claims for $1000. Many of these sales were effected, and it is not unlikely that litigation will follow.

Going into Steamboat the activity starts at Hope. That town has awakened after outdoing Rip Van Winkle twice over. Forty years ago it was in the throes of excitement because of the Cariboo discoveries, and now all the buildings in the place are crowded and a tent town has been established. New hotels are being erected and effort is being made to take care of the traffic. Two road-houses, one at Fourteen-Mile and the other at Twenty-Three Mile, supply the needs of travelers on the trail. The road is not the best, but will be improved this year. The best way in is from Princeton on the east side. As this latter may have been a stringer, it is not taken into calculation. Assays are now being made of the other ore brought in.

Besides the Steamboat Gold Mines, the Steamboat Wonder has good claims on Steamboat mountain, and several others are being opened up. The Steamboat Central's property is on Red mountain, and Fred Whitwell has the Yellow Jacket there also. On the west bank of the Skagit, almost opposite, Messrs. Moore and O'Neill and the Steamboat Prospecting Co. are preparing to work their claims on Luckless mountain. Down near the boundary Mr. Webb and associates, of Seattle, have a promising location and prospecting is lively.

Steamboat is the last great area of mineral ground in the southern part of British Columbia that is practically virgin ground for the prospector. All that remains now is to prove whether there is gold in the sulphide zone as well as in the rich surface oxides. The trials of a new camp are bound to come, but it is expected now that Steamboat will come through all right.

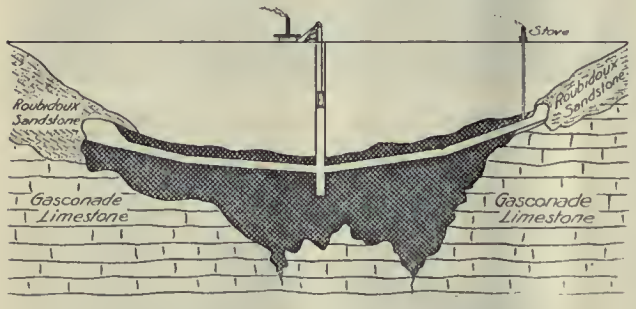
Hematite Deposits of the Ozark Uplift

By Norman L. Ohnsorg

The hematite deposits of the Ozark mountains are generally situated along the back-bone of a ridge and are characterized by a promontory on the ridge, the orebody being the cause of this irregularity. The orebodies are in sinks formed by the leaching away of the underlying Gasconade limestone and the bending down of the overlying Roubidoux sandstone into these caverns, followed by a leaching out of this sandstone and deposition of the hematite, coming from a higher ferruginous horizon. The contact, when seen near one of these sinks, of the Roubidoux sandstone and the Gasconade limestone may easily be mistaken for an unconformity, the limestone lying nearly horizontal, while the sandstone has a dip of 10° or more.

Profits of Mining

Where these deposits are close to the surface they are mined as open-cuts. The shallow deposits are practically exhausted and the deposits are now being worked as underground mines by a modification of long-wall retreating or the caving system. A shaft having been sunk in the centre of the deposit and drifts run to the extremity of the orebody at the highest level, the ore is taken out and the ground above allowed to settle; the next lower level then being worked, if the thickness of the orebody permit.



CROSS-SECTION, MISSOURI HEMATITE DEPOSIT.

In general these deposits do not permit of more than one level. The ore around the shaft is taken out last. The saving of ore by this method is very high. The old method probably saved less than half.

Extensive timbering is necessary, due to the loose texture of the overburden. Timbering is not expensive, however, as the country is heavily wooded. White oak mine timbers can be had for little more than the cost of cutting. Drilling is done entirely by hand. The cost of labor is $1.25 to $1.50 per day for underground men. As the ore consists of hard lumps in softer material, and is full of clay seams, it does not permit of the use of air-drills, and for this reason ventilation becomes quite a problem.

Combined Method of Prospecting and Ventilation

After the mine has been located the centre and general outline of the deposit is determined by plotting up the dips. The orebody is then proved by means of a churn-drill; an 8-in. hole is commonly put down, at intervals of 100 ft. or more, so placed that during the development and working of the mine these holes can be used for ventilation. The cost of drilling ranges from 80c. to $1.25 per foot, depending on the size and depth of hole.

An ordinary large sheet-iron stove, having a circular 8-in. draft opening, is used for securing ventilation. When the mines are damp or cold, which is seldom, as they have a natural drainage through the sink, pumping rarely being necessary, the stoves are placed in the mine, using the drill-hole as a flue; but in most cases these stoves are placed on top of the ground and the draft connected to the drill-hole casing, getting its air for combustion from the mine. When a good strong fire is kept in these stoves, the results are remarkably good. This same method is employed in shaft-sinking, using a canvas sleeve on the lower end of a suction pipe. The best results are obtained, however, by having the stove underground, as the draft being close to the floor takes out the heavier gases, such as carbon dioxide. Before this method of ventilation was adopted but one shift could be worked, and even then much time was lost when it was necessary to shoot during the shift.

It would seem as though there should be a large profit in mining these ores, with cheap labor, low cost of timber, and other items in proportion, but the profit is actually small, the operator receiving about $2.25 per ton f.o.b. railroad at mine, for ore carrying 58% metallic iron. Where the mines are operated on a lease, a royalty of about 25c. per ton is paid, and it takes good management to make them pay, as they are not found along the railroad. Those large enough to warrant it have their own sidings built from the main lines.

Fusions

By H. C. Pritham

Any method of running a fusion around a crucible to cool takes time and care to perform the operation, and in the subsequent digestion in hot water the fusion dissolves slowly, and if, as sometimes happens, considerable of the fusion collects in a hard mass in the bottom of the crucible, it certainly takes time and patience to get it dissolved out. With the following method all this is avoided. The crucible is almost entirely clean from the fusion and the dissolving of the bottom is very fast. The minimum of time is required to transfer the liquid fusion to the digestion in hot water. Many times in a commercial laboratory or a cement plant one has to fuse 20 or 30 samples of clay or other material in the morning, and as a rule has about four platinum crucibles to do the work in. The sooner the chemist can make a fusion and get a clean crucible back, the more time he will have to sleep that night. Moreover, the wear and tear on the platinum is much less. The sudden chilling of a crucible in cold water or the squeezing in of the sides in order to loosen a fusion is not beneficial; the platinum gets brittle and loose. Considering the present price of $43 per ounce it is necessary to take care of the crucibles.

My method is to take a shallow 5-in. evaporating dish and bend up a clay triangle so as to set in the centre of this. In the triangle put a 50 c.c. nickel crucible so that it is held solid and leaves about an inch space between the bottom of crucible and dish. Fill the dish with cold water up to the triangle, and you are ready.

When the fusion is finished raise the heat for a minute or two, remove the cover and at once pour the fusion into the nickel crucible by taking up the platinum crucible in the forceps on one edge. This can be done very quickly and easily with practice. Almost all fusion will pour out and will solidify at once. Have a casserole ready half full of hot water, pick up the nickel crucible in the forceps, tap it lightly on the desk, and dump the button into the casserole. Keep the casserole covered. The action of the hot water on the hot button will disintegrate it. Add the platinum crucible and cover, and after a few minutes take them out and rinse off. If necessary, rinse in acid into a beaker, using this acid when the fusion is made acid for evaporation. Acid should not be added, however, until the fusion is well dissolved. The button will leave the nickel crucible clean, but if desired it can be rinsed in hot water. If this is done be sure to have the crucible perfectly dry before pouring the next fusion. A little water will cause rather startling results when the hot fusion is poured in on it.

In conclusion I would call attention to the fact that a blast-lamp is not necessary for fusions, contrary to most textbooks. A good Bunsen burner will give all the heat needed except in a few iron ores. The heat should be low until the fusion is well under way. In no case should the practice of turning on a blast-lamp for fifteen minutes be allowed.—*The Chemical Engineer.*

Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

GLASS may be cemented to iron by melting 1 oz. wax and 5 oz. rosin on a water bath, and adding, with constant stirring, 1 oz. venetian red, previously well dried. The mixture should be stirred until nearly cool, so as to prevent the venetian red from settling to the bottom.

RUST is removed from instruments by laying them over night in a saturated solution of chloride of tin. The rust spots will disappear through reduction. Upon withdrawal from the solution the instruments are rinsed in water, placed in a hot soda-soap solution, and dried. Cleaning with absolute alcohol and polishing chalk may follow.

INKS for marking articles of glass, glass slips for microscopy, reagent flasks, etc., are as follows: in black, sodium silicate one to two parts, liquid india ink one part; for white, sodium silicate three to four parts, chinese white one part. Instead of chinese white a sufficient amount of the so-called permanent white (barium sulphate) may be used.

A SOLUTION for water-jackets on gas engines that will not freeze at any temperature above 20° below zero (F.) may be made by combining 100 parts water, by weight, with 75 parts carbonate potash and 50 parts of glycerine. This solution is non-corrosive and will remain perfectly liquid at all temperatures above its congealing point.

SCREW connections may be made tight by using powdered shellac dissolved in 10% ammonia. The mucilaginous mass is painted over the screw threads, after they have been thoroughly cleaned, and the fitting is screwed home. The ammonia soon volatilizes, leaving behind a mass which hardens quickly, makes a tight joint, and is impervious to hot and cold water.

SHEET MICA properly dressed, varying in sizes from 1½ in. diam. upward, has an average value of 24c. per pound. Scrap mica, which includes all sizes below 1½ in. diam., sells for about $14 per ton on the Pacific Coast. Buyers require this material in a finished state, and it is a serious question whether there is sufficient demand to justify the erection of a plant.

LABELS may be attached to glass bottles by using water glass (sodium or potassium silicate). Care should be taken to spread this product on the glass, not on the paper, and then to apply the paper dry, which should be done immediately. When the solution is dry, the paper cannot be detached. The silicate should be somewhat diluted. It is spread on the glass with a rag or a small sponge.

FLAKE GRAPHITE commands very good prices if the material is properly dressed and sized. Crude amorphous graphite is used in limited quantities, and it is a question whether there is sufficient demand on the Pacific Coast to keep one fair-sized mine in operation. Most of the miners of amorphous graphite are forced into the manufacture of pencils, etc., to get rid of their output.

THE FOLLOWING PREPARATION will remove rust when already present, and prevent its coming, if the article is well greased with it. Melt 5 parts crude vaseline on a water bath, and mix 5 parts finely levigated powdered pumice stone into a uniform mass. To the half-cooled mass add one-half part crude acid oxalate of potassium in a finely powdered state and grind into complete homogeneity.

PLATINUM is easiest recovered from black sands by simple washing operations, for it is as easily recovered as gold and can be caught in the same way, with the exception that it will not amalgamate unless some strong reagent, like sodium amalgam, is employed. When platinum occurs with copper or nickel it is finally obtained in the refining of these metals, but the methods employed are complex and expensive and could not conveniently be used except at a large plant.

WORKING DESIGNS and sketches are easily soiled and rendered unsuitable for further use. This can be avoided by coating them with collodion, to which 24% of stearine from a good stearine candle has been added. Lay the drawing on a glass plate or a board, and pour on the collodion, as the photographer treats his plates. After 10 or 20 minutes the design will be dry and perfectly white, possessing a dull lustre, and will be so well protected that it may be washed off with water without fear of spoiling it.

IRON AND STEEL may be coated with glass by melting together 125 parts (by weight) of flint-glass fragments, 20 parts sodium carbonate, and 12 parts boracic acid. The molten mass is next poured on a hard and cold surface, stone or metal. After it has cooled, it is powdered. Make a mixture of 50°B. of this powder and sodium silicate (water glass). The metal to be glazed is coated with this and heated in a muffle or any other oven until the mixture melts and can be evenly distributed. This glass coating adheres firmly to most metallic surfaces, especially to iron and steel.

CALCITE veins, like quartz veins, have no essential connection with valuable ore deposits. Quartz and calcite are the commonest fillings of fissures because these minerals are the ones most commonly deposited from circulating solutions. When these solutions contain valuable minerals as well, the resulting deposit is very large compared with the cases in which it contains workable ore deposits. In the Cobalt region the minerals occur in calcite veins, but in many other districts calcite veins have no particular significance. The fact that there is no calcite in the adjacent rock merely indicates that the solutions have derived their mineral content at a distance.

A GOOD FURNACE JACKET may be prepared in the following way. A piece of asbestos millboard—10 by 4 by ⅜ in.—is perforated in about a dozen or more places with glycerined cork borers, then nicked about an inch from each short end and immersed in water until saturated; next the board is bent from the nicks at right angles and the perforated portion shaped by bending it over a bottle with as little force as possible. The result should be a perforated arched tunnel, resting on narrow horizontal ledges at each side. Dry this cover in the furnace, after setting it in position, and pressing it well to the supports. Three such covers, weighing one pound, replaced 24 fire-clay tiles, weighing 13 lb., and a higher temperature was obtained than with the latter.

GEM-STONES must possess three characteristics to fit them for purposes of ornament. They must be hard, so that their brilliancy will not be lost by the wearing away of the sharp angles and surface of the cut gem. They must be of uniform color throughout (except some semi-precious stones, where the difference in color are such as to make them attractive); and, finally, they must have a pleasing color. In most cases they must also be transparent or translucent, and free from flaws; though some semi-precious stones, such as coral and jet are opaque, and in others, such as aventurine and cat's eye, the presence of foreign material gives the gem its value. In gem deposits, diamond-bearing earth, for example, only a comparatively few of the stones found have a good enough color and are free enough from defects to yield cut diamonds of the best quality. The inferior stones are utilized in a variety of ways.

Discussion

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

Republic Mining District

The Editor:

Sir—In your issue of May 13, 1911, M. H. Joseph comments on plate XI of Bulletin No. 1 of the Washington Geological Survey, and presents many interesting facts concerning the relative importance of gold and silver, with depth, in the Republic veins; facts largely brought to light by developments since that paper was written. It may be worth while, however, to outline the manner of securing the data upon which the figure in question is based. From the records in the company's office, assays from the four levels were picked at random by an officer of the company and called off to myself, who recorded and averaged them. *Every* assay of the 107 thus secured appears in the average for the level to which it pertains. The ratios of gold to silver in ounces for the various levels thus appear to be: Glory Hole, 1 to 1.09; 203-ft. level, 1 to 2.45; 385-ft. level, 1 to 4.19; 565-ft. level, 1 to 6.19.

Figure 5 of the same report illustrates a similar condition in the Lone Pine mine. Here the *total number of ounces of silver and of gold* derived from all ores extracted above No. 2 level and the total derived from below it are used in securing the ratio. The relation of gold to silver thus secured is as 1 to 5.6 above No. 2 level and as 1 to 8.6 below No. 2 level.

It is noteworthy that most of Mr. Joseph's citations are from the Quilp-Surprise vein. On page 54 of the bulletin the following appears: "The Quilp vein has been explored 600 feet on the dip and continues north as the Surprise vein, while to the south it has not been identified. * * * Above the 100-foot level gold was to silver as 1 to 12.19, while at greater depth the ratio was as 1 to 6.08. It will be noted that this is the reverse of the rule for the camp, for in all other mines where data were available, the ratio by ounces of gold to silver decreases with depth. The incongruity may possibly be explained by a local concentration of silver in the upper levels." In referring to the same vein, Mr. Joseph states that "in February a deposit of ore was found on the 50-ft. level of the Quilp mine that was exceedingly rich in silver, from which, in fact, the finest specimens of native silver ever seen in the camp were taken."

To me plate XI and also Fig. 5 would suggest secondary enrichment of silver, but since other lines of evidence supporting this suggestion were not found, it seemed wise to present only the facts in the report. The Republic deposits, excepting the New Republic and Princess Maude, are very tight. This is especially true of the Quilp-Surprise vein, yet in this Mr. Joseph reports the recent discovery of native silver, a mineral generally, if not always, of secondary origin. Evidence of this sort did not appear during the investigation, but if found to be generally true it should be taken as proof that secondary enrichment of silver has taken place. Thus if the New Republic vein should be explored at greater depth and the averages of assays from lower levels subjoined to plate XI, it might very possibly show the silver area to close in and continue more nearly parallel in amount to that of the gold. It would seem that with recent extensive developments on the Quilp-Surprise vein—developments reaching several hundred feet below the bottoms of adjacent gulches and this below the level where secondary agencies have probably been effective—excellent opportunity is offered for constructing a similar figure which would combine the relations existing both within and below the zone traversed by the more active meteoric circulation. Since the Republic deposits are bunchy, care should be taken to compare only *broad* averages, and those should be from the *same* ore-shoot.

In brief, the figures represent relations in two important mines of the camp, and the statements refer to these figures and also to conditions said to have been met in other Republic properties. Although later developments may modify the conclusions stated in the report, yet it is firmly believed that they are correct so far as they go. If applied to the camp as a whole, I cannot agree with Mr. Joseph that the ratio of gold to silver has "no relation whatever to depth."

JOSEPH B. UMPLEBY

Washington, May 23.

Surface Indications of Ore-Shoots

The Editor:

Sir—Lorenz von Schoen, in your issue of May 27, has called attention to a condition frequently found in the desert regions. It is not an uncommon thing to find a well defined vein, consisting principally of quartz, in which pay-shoots occur, the limitations of which are of surprising sharpness, the valuable contents, metallic sulphides, as well as gold and silver, seeming to have been deposited in and confined to the sharply defined zone in which they are found, by some influence difficult to determine, while the barren quartz continues without any apparent reason for the difference. Occasionally there is incontestable evidence that a barren zone has at one time been mineralized, from which through some process of leaching, the minerals, both base and precious, have subsequently been dissolved and carried away in solution to be redeposited elsewhere. Such places generally give evidence that chemical processes have been at work, as shown by the porous or honey-combed condition of the vein material. Often the character of the mineral removed may be determined by the shape of the open spaces left in the quartz or other gangue. This is particularly true of pyrite, the dissolution of which often leaves hollow cubes which occasionally contain native sulphur, due to the incomplete removal of the sulphur of the pyrite, which may or may not have contained gold. Gold, however, is not always left in these hollow places, even when the original pyrite was auriferous. Pseudomorphs after various minerals are of frequent occurrence in these leached zones, especially limonite replacing pyrite by oxidation. If the original pyrite were gold bearing, then the limonite is likely to be also, though, like the hollow spaces, it is not invariably so. Occasionally these limonite pseudomorphs are far richer in gold than any of the normal pyrite that can be found, and this is not so easy of explanation, except upon the theory of 'secondary enrichment', a condition often occurring, but really little understood. Equally strange and unaccountable is the sudden termination of the occurrence of gold and silver in a vein of sulphide ore when the sulphides are found to continue without interruption, although it is true that in such cases there is generally a noticeable change in the character of the sulphide. I know of an instance in Yavapai county, Arizona, where a vein 1 to 4 ft. wide has a pay-shoot carrying sulphides of iron, copper, lead, and zinc, the pay in which quits within a foot, the mixed sulphides with their gold and silver giving place to a vein of solid pyrite 4 ft. wide, but which is almost destitute of gold and silver, as well as the sulpbides of the other metals mentioned. In this instance the pyrite, which was granular and loosely coherent, acted as a gangue mineral in practically the same manner in which quartz acts. When barren quartz is found to succeed a pay-shoot in a well defined vein, it is not always certain that the barren quartz has at one time been rich, for it may always have been in the condition in which it is found. Pay-shoots are often very erratic in their distribution in a fissure, and the reasons for their occurrence where they are found, and for their more or less sudden ending, when their limits are reached, are beyond positive knowledge, notwithstanding the many theories that have been advanced to account for them. It is not always the influence of geological conditions that results in the formation of a gulch, at the surface, that is responsible for the ending of a pay-shoot. More often the pay ends without apparent cause. In the Yander-

hill district at the north end of the New York mountains, that may be considered as a northeasterly extension of the Providence mountains, the ore-shoots occurred independently of each other in a fissure that could be traced along the surface for many hundreds of feet. The walls of the fissure were from 3 to 4 ft. to over 20 ft. apart, and the material between consisted principally of clay resulting from the crushing and complete alteration of the feldspathic minerals of the zone of shearing. This clay 'filling', as it was called, was split by a rude cleavage parallel to the walls of the fissure, due to subsequent pressure. Within this zone of fissuring, crushing, and alteration the pay-shoots of ore were formed. They overlapped each other both horizontally and vertically, their edges thinning out like a wedge. From 1 to 3 ft. of clay was usually found between the overlapping ends of these shoots. Incidentally, it is interesting to mention that these shoots terminated at the surface, upon reaching a gulch which crossed the strike of the vein. I inspected these ore-shoots and could see no reason why the several shoots had not formed as a single long and deep shoot, instead of a succession of comparatively short and shallow ones. There are a great many ore-shoots that do not come within hundreds of feet of the surface, although the fissure in which they occur is continuous for hundreds and in some instances for thousands of feet, both horizontally and in depth. In numerous instances the reason for the existence of an ore-shoot at a certain place can be stated with reasonable assurance of being correct, but there are a great many cases where no reason susceptible of demonstration can be given.

WILLIAM H. STORMS.

Berkeley, California, May 30.

The Editor:

Sir—The question propounded by Lorenz von Schoen in *Mining and Scientific Press* of May 27 is a difficult one to solve. That nearly all orebodies have these barren zones and spots within the shoot is a well recognized fact, but the cause of this has never been entirely explained. In some districts this condition can be easily explained by demonstrated facts; in others, all signs fail. I have found in the zone of weathering that surface waters would completely leach out the values in some parts of the vein only to enrich other portions. If a barren zone is encountered above water-level and the filling is crushed and loose-textured, or shows large quartz crystals of perfect shape, or a thin watery mud between the cracks of the gangue and a less amount of oxide stains than in the orebody, then a further sinking or driving is advisable. If the workings are below water-level in the zone of primary mineralization and the ore changes to barren gangue of the same composition as that in the ore-shoot, and the wall-rocks are still uniform, then both hanging and foot-wall should be exposed by short cross-cuts. If either wall shows a low undulation or swell toward the vein, but without pinching the same, and the filling is either harder or crushed more than the ore, then it is favorable for further exploration, vertical or lateral. These are personal observations from widely scattered districts and are not given as a rule. Every prospector should study the known facts about ore deposition, as by so doing he will avoid many a useless blow on a hand jack, and, conversely, will not be afraid to open up that which his added knowledge tells him is worth while.

Cazadero, California, May 29. R. L. MANN.

Federal Control of Water-Power Sites

The Editor:

Sir—There is much in your editorial in the issue of May 13, referring to the recent decision of the U. S. Supreme Court as to jurisdiction over Federal lands, with which I agree. But not with your statement, "There is a general impression in the East that the people of the West do not favor Federal control of water-power sites," as being a wrong impression. Insofar as Federal control of water-power sites or any other control of waters except for navigation purposes, which has been assumed by withdrawal of power sites, and control of the waters on forest reserves by Federal authority is concerned, I believe the people in the East are correct in their estimate of Western objection. Furthermore, the recent decision in no manner affects the right of control of waters or water-powers which had long since been passed upon by the highest legal tribunal of our country and confirmed State control. It will be remarkable indeed if notice is not served upon the Federal Government by State officials where the right of the State to the use and control of the waters therein is questioned, or an attempt is made to abrogate that right by the Federal Government or by any bureau thereof. Legislation which has been passed upon this subject by Congress is held of no legal force in face of other evidence bearing upon this question.

L. K. ARMSTRONG.

Spokane, Washington, May 20.

[Our understanding of the present situation as regards State and National authority over waters is that announced by the President; namely, where the Government owns the land upon which dams must be erected in order to utilize the waters, there is no necessity to inquire further. This position is made stronger by the Supreme Court decision, which confirms in the broadest terms the right of the Government to hold and to use Federal land in any manner Congress may see fit. The States have control of the water to the extent that such control is separate from land ownership, but no State can force the Government to sell a water-power site, whereas it is quite possible for it to force a private owner to do so. Whether Western sentiment would or would not endorse a reasonable control of such matters by Federal officers is admittedly a matter of opinion. Our own judgment is that prompt formulation of a reasonable plan would greatly relieve the situation, and we have found sentiment generally much more adverse to the present plan of withdrawal by a non-user than to the idea of Federal control itself. To prevent any possible misunderstanding, we repeat that this all applies only to water-power and mineral resources on land belonging to the United States, not to land privately owned.—EDITOR.]

Coal Production of Kentucky

Kentucky is the only one of the United States whose coal supplies are drawn from any two of the great fields. The eastern counties of the State are underlain by the coal measures of the Appalachian region, and the southern extremity of the eastern interior or Illinois-Indiana field is worked extensively in the western part of Kentucky. Coke, according to E. W. Parker in an advance chapter from 'Mineral Resources for 1910,' published by the United States Geological Survey, has been made from coal mined in both the eastern and western parts of the State; but, although the coals of the eastern counties are in large part included among the high-grade coking coals of the Appalachian field, and although little or no coke is made from the coals of the eastern interior field in Illinois or Indiana, the larger part of the coke made in Kentucky has been made in the western district.

Kentucky's coke production in 1910 amounted to 53,857 short tons, valued at $120,554, against 46,371 tons, valued at $101,257, in 1909, an increase of 7486 short tons, or 16.1 per cent, in value. The average price per ton advanced from $2.18 in 1909 to $2.24 in 1910. The quantity of coal used for coke-making in Kentucky in 1910 was 104,103 short tons, principally slack.

OF THE 2,069,266 short tons of coal used for coke-making in Colorado and Utah in 1910, 1,387,070 tons was cleaned by washing before being charged into the ovens. The washed coal included 836,067 short tons of mine-run and 551,003 tons of slack. In addition to the washed slack, 429,728 tons of unwashed slack and 252,468 tons of run-of-mine coal were used unwashed.

Mines of Western Australia

The following table gives the production for 1909 and 1910 of some of the leading mines of Western Australia:

ASSOCIATED

	Tonnage.	Value.	Profit.	Dividends.
1909	134,725	$1,250,000	$329,500	$245,000
1910	128,181	878,500	41,000*	.....
To date ...	1,252,823	15,925,000	.....	3,400,000

ASSOCIATED NORTHERN BLOCKS

1909	44,163	$407,500	$150,000	$162,000
1910	28,721	246,000	.....	87,500
To date ...	339,806	8,000,000	.....	3,410,000

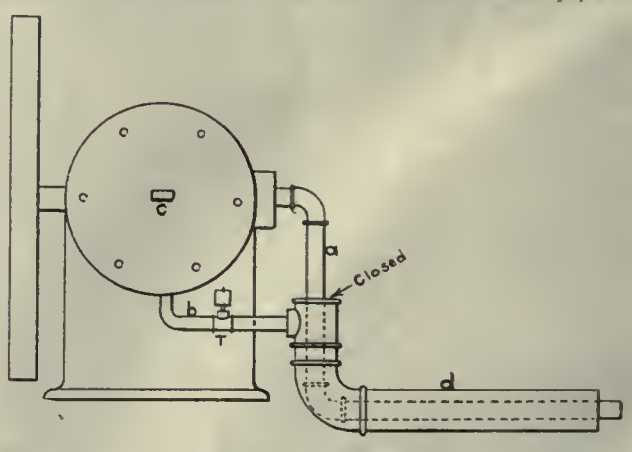
Inlet-Air Heater for Gasoline Engines

By E. R. RICE

In the mining camps situated on the desert, where fuel and water are scarce, the gasoline engine is quite generally used for hoisting and for miscellaneous power. It is often said that a gasoline engine has more whims than a pretty woman, but it has been my experience that it is as reliable as a steam engine, if properly taken care of. The greatest trouble with a gasoline engine occurs during cold weather, for then the gasoline is vaporized with difficulty. This is specially true for the engines that use 48 to 50° distillate, instead of the 72° stove gasoline. For perfect combustion, the gasoline should be in the form of a gas, and it will be readily seen that this condition is easier brought about if the inlet-air is hot. I have found the following scheme efficient in overcoming the difficulties due to too cold inlet-air.

In the figure, *a* is the exhaust-pipe of the engine, which passes through a larger pipe *d*. The pipe *d* should be about twice or three times the diameter of the exhaust pipe *a*.



INLET-AIR HEATER.

The inlet-pipe is shown at *b*, and is connected to *d* by means of a T and suitable reducers, so that when a fresh charge of air is drawn into the engine, the air has to pass through the pipe *d* and around the hot exhaust-pipe *a*. The carbureter is shown at *c*, and the air entering through *b* passes around *c* and the gasoline is drawn into the cylinder in the form of gas.

An engine will produce more power for a certain size of cylinder and certain speed if the inlet-air is cool, but an engine will produce a horse-power hour with less gasoline if the inlet-air is hot. Unless the engine is run up to its total capacity, it is economical to heat the inlet-air. Most gasoline engineers keep the jacket-water fairly cold. This is a mistake and the jacket-water should be kept hot. I prefer to have the jacket-water at such a temperature that I can just hold my hand on the overflow pipe for a moment without it burning my hand.

Gasoline engines are usually started by hand, compressed air, or by exploding a charge of gas in the cylinder. In

cold weather it sometimes happens that after the initial explosion, the engine will fail to explode the succeeding charges of lower-grade distillate that is generally used in the larger engines. This difficulty can be overcome by putting a T in the inlet-pipe as shown at *T*, and by means of suitable reducers, an ordinary sight-feed lubricator is connected to the T. This lubricator is filled with high-grade gasoline, and the gasoline fed directly into the feed pipe. As the engine draws in a fresh charge, the high-grade gasoline is readily vaporized and is drawn into the engine cylinder and easily exploded. As soon as the inlet-air and engine become warm enough to vaporize the regular distillate, the lubricator is closed. In the figure here shown, the right-hand fly-wheel is omitted so as to avoid confusion in the drawing.

Waihi Grand Junction Mine

STAFF CORRESPONDENCE

The history of this mine affords one of the most notable examples of a new manager turning a previous failure into a success, and William Frank Grace deserves a place in the roll of fame. The company was formed as long ago as 1895. Three of the lodes found in the Waihi mine continue into the Grand Junction territory, namely the Martha, Royal, and Empire. For many years the results of development work were disappointing and much capital was spent to no purpose. F. C. Brown, the manager, was succeeded at the end of 1909 by Mr. Grace, who had previously reported on the property for people intending to supply further capital. The results during 1910 show that Mr. Grace has effected a radical change all round, and that the position and prospects of the mine have been improved out of all recognition. He did 13,092 ft. of development work during the year, as much as in the three previous years put together, and he increased the ore reserve by 71,750 tons, besides sending 84,226 tons to the mill, which was a far larger yearly extraction than ever before recorded. At the same time the working cost, excluding development, has been reduced from 22s. 10d. to 15s. 3d. per ton. The cost of mining was reduced from 12s. 6d. to 7s. 7d. by altering the method of payment from footage of holes drilled to tonnage extracted, and the treatment cost was lowered by shortening the time occupied in air-agitation with a consequent reduction in cyanide consumption. As already stated, 84,313 tons was sent to the mill; from this, gold-silver bullion worth £133,315 was recovered. Mr. Grace does not report the separate gold and silver output, but I presume that the relative proportion of the two metals is the same as at the Waihi, though the total content is rather less. The profit for the year was £30,646 and a dividend at the rate of 5% has been paid, the first dividend ever earned. Mr. Grace's report is of great technical value, as it describes many interesting points in connection with milling in cyanide solution, all-sliming in tube-mills, and air-agitation. In writing this account of Mr. Grace's doings there is no desire to disparage the previous manager, F. C. Brown, in any way. Mr. Brown is a well-known engineer and is the inventor of the Pachuca agitator.

TO DETERMINE, if possible, why zinc ore prices are not as strong now, compared to the price of spelter, as they have been in the past, the Joplin Commercial Club has appointed a committee headed by P. L. Swartz to make an investigation. One interesting report has been made. Seven smelters buying zinc ore in the Joplin district, utilize the by-product, sulphuric acid, according to the committee. Last year the production of sulphuric acid from Joplin ore was 100,000 tons. The approximate valuation was $1,000,000, the wholesale price at which the acid was sold having ranged from $6 to $14 per ton. When refined the product sells for as high as $150 per ton, which would bring the acid up to $10,000,000 to $15,000,000, or about as much as the total paid for all ores—blende, calamine, and galena—shipped from the Missouri-Kansas-Oklahoma district in a year.

Tin

Straits shipments of tin for May, as reported by L. Vogelstein & Co., were 4310 tons; United States deliveries, 3400 tons. London and Holland deliveries are estimated from 2200 to 2400 tons, as usual, and the visible is expected to increase about 1500 tons—to 16,000 tons—which is 3000 tons less than a year ago when the price was £150. The position has improved 16% and the price 40%. It is useless to make comparisons of this sort, it being well understood that the present price is due to a corner, as shown by the decrease in price of £20 per ton. It may be useful, however, to review previous experiences of the same sort, as, for instance, during the Secretan corner in 1888 as follows:

	Spot.	Futures.
April 27	£166	£110
April 30	106	No price
May 1	92	No price
May 7	80	£80
Again, in 1907:		
July 5	£200	£181 10s.
July 31	182	181
August (low)	163 10s.	
September (low)	159 10s.	
October (low)	137 5s.	
November (low)	134 5s.	
December (low)	115 10s.	

Whether or not history will repeat itself is hard to foretell. It would be best to have the tin market return to a normal basis where it could be traded in like any other staple, and it is likely that this will happen in due time. With tin up and rubber down, the mines will again attract the labor from the plantations, and the small falling off in Straits shipments will soon be made good. By the end of June it will doubtless be counterbalanced by the falling off in American deliveries, besides the increase in quantities of tin coming forward from sources other than Straits, particularly Bolivia and China. In a recent report, G. E. Anderson, U. S. Consul at Hongkong, China, predicts that the introduction of improved modern machinery now being set up in Yunnan province "will probably double the output of the mines in that vicinity at once," adding "the ore deposits are known to be very large and of high quality, and production is likely to be expanded as much as the world's markets will justify."

Copper

The copper market is fairly firm. Some 60,000,000 lb. was sold for export during May, and while production has not decreased, it is expected that the producers' report will make a good showing. Domestic demand has been somewhat improved and a large aggregate of small-lot buying has been a feature. The Lake Copper Co., which was skyrocketed so violently in the Boston market last year, is again bidding for attention. Some of the best indications yet found on the property have been found by the diamond-drill.

Butte is adding its weight to the copper situation by the opening of rich orebodies in the North Butte at 2200 ft., in what is thought to be the Berlin vein, and in the Tuolumne a cross-cut has penetrated what is thought to be the extension of the Edith May vein of the North Butte. Ohio Copper is struggling for recognition as a real porphyry. The mill is handling some 1400 tons of ore per day and is making about 60,000 lb. of copper per month. Comparing this with a property such as Tuolumne, which puts out about 100 tons per day and produces nearly 1,000,000 lb. monthly, demonstrates the necessity for large and continuous operations by the low-grade milling copper producers. The United States Geological Survey's preliminary estimate places the 1910 production of refined copper in the United States at 1,422,039,135 lb., compared with 1,391,021,454 lb. in 1909, an increase of 31,017,681 lb., and the largest output in the history of the industry.

Special Correspondence

JOPLIN, MISSOURI

ZINC ORE PRODUCERS PERPETUATE CO-OPERATIVE ORGANIZATION.—PECULIARITY OF UNDERGROUND WATER CIRCULATION.—REJUVENATING A PIONEER TRACT.—CHICAGO BANKER ENTERS DISTRICT.—ZINC AND LEAD NOTES.

Zinc ore producers of the Joplin district have decided to perpetuate the organization which was launched a year ago. The membership includes operators in Missouri, Kansas, and Oklahoma. New Officers have been elected as follows: John R. Holmes, president; J. L. Bruce, vice-president; W. B. Shackleford, secretary; Howard Murphy, treasurer. B. K. Blair was re-elected active secretary. Through the Zinc Ore Producers Association, as the organization is known, operators believe they have been materially benefited. One of the chief objects of the association has been to gather data relative to zinc ore prices, and this information has been given to the members. Operators claim they have been enabled to secure much higher offers for their ore than otherwise would have been the case. The bulk of zinc ore is sold in open market to the highest bidder, and inside information on market conditions often makes it possible for the producer to command a much better figure for his output. Efforts to persuade the producers to accept the contract system of selling ore on a metal basis are to be continued by the association.

Mine tailing, emptied into a natural cave-in at the Mary C. mine in the Thoms Station camp, north of Joplin, has checked the heavy underground flow of water which had made pumping operations at the Federated Co.'s mine, 1½ miles to the east, a herculean task. This shows to what extent the drainage area of a Joplin mine may reach. Pumping at the Mary C. mine several months ago is thought to have exhausted the water in an underground reservoir and caused the surface to drop in, several hundred yards east of the workings. The pit thus formed afforded an excellent place in which to empty the mill tailing. As these began to accumulate in the pit it was noted that pumping at the Federated mine became less and less difficult. At the Mary C., on the other hand, the volume of water handled has increased. Other similar instances are reported from Thoms Station. When Frank Nicholson's Catharine mine was started, wells two miles to the north went dry and farmers threatened to sue for damages. A satisfactory settlement was made by the mining company. In new camps it is often noted that springs disappear with the beginning of deep pumping operations.

Drilling and shaft-sinking on the Connor estate in the Prosperity camp, east of Joplin, have revealed rich deposits of zinc and lead in a district which was a heavy producer in the pioneer days, but which has remained idle for many years. The finding of zincblende in a shaft 850 ft. east of John Durby's concentrating plant, which has been idle for months, will result in the renewal of activity at this mill. The ore will be trammed to the concentrator from the new shaft. Zincblende, running better than 50% of the dirt hoisted, has been found in a formation 14 ft. high. The extent of the deposit has not been determined by drill-holes, but at present it is regarded as one of the best finds of the year. This ore is found just west of a limestone bar which marked the western boundary of the famous Mt. Ararat mine, which was a heavy and consistent producer for many years. A similar strike has been made by a company operating on the old Monticello lease of the Connor land, farther to the north. Here, a limestone bar marked the north limits of the mine. Drill-holes sunk a short distance farther north have gone into good blende and galena, indicating that the bar was thin. The big Monticello mill was moved away.

Work at the Minor Heir mine, in the thin sheet-ground district north of Webb City, is to be resumed by W. M. Sheridan, president of the W. M. Sheridan Co., of Chicago, who has made several trips of inspection to the district. The Minor Heir is near the Yellow Dog, the Bull Dog, and the Red Dog, and is in the heart of what is known as the 'Dog' district, one of the steadiest sheet-ground areas north of Webb City. A sheet-ore face from 9 to 12 ft. in height is to be developed. The mine is equipped with a 250-ton concentrating plant. Mr. Sheridan has acquired the Cooley farm of 160 acres, in virgin territory north of Joplin, and will thoroughly prospect it with a drill.

For years, the John Jackson mine, in Chitwood, a suburb of West Joplin, was the richest zinc producer in the entire district. Then it suddenly went 'blind'; that is, blank limestone walls loomed up where good ore had formely been found. A few prospect drifts were driven into the blank walls, and then operations were abandoned, the big mill removed, and for years the John Jackson land produced nothing. Today it is among the leaders in the production columns of the Joplin camp. It is a perpetual contest between the Granby land, with a half dozen mills, and the John Jackson land, with less than half as many mills, which shall lead the weekly statistics. This shows that a 'blind' mine is not necessarily a dead mine. The John Jackson tract has been acquired by the St. Louis-Joplin Lead & Zinc Co., and in addition to the heavy production now coming from the old drifts of the John Jackson and adjoining leases, a new formation has just been opened in the Goodenough mine, a few hundred yards to the west. Here the ore is found on two levels, the upper ground being soft and pockety, while the lower is a typical sheet formation. A new zinc district, recently opened south of Shoal creek, in the Galena, Kansas, camp, is developing into a lead district as well. In the mine of the Clermont company galena has been found at a depth of 185 ft. The deposit is being blocked out and is proving to be extensive.

DENVER, COLORADO

A GRUBSTAKE FUND.—METHODS OF PROSPECTING.—THE STATE SCHOOL OF MINES.—POLITICS AND EDUCATION.—CRIPPLE CREEK ITEMS.—DRAINAGE TUNNEL EXTENSION.

The committee on mines and mining of the Denver Chamber of Commerce has started a campaign to raise a grubstake of $10,000. The idea is to outfit several prospecting parties to search for new camps. The contributions to the fund are reported as generous, and it is hoped that the desired find will be made. The dearth of prospectors has become a threadbare topic. Other and more attractive regions have claimed a few of our prospectors. The Forest Service has been accused of driving the timid, defenseless prospector from the public domain in Colorado. Many other reasons of more or less importance have been adduced to explain why the old-time burro outfit is such a rarity. The fact is that there are as many prospectors in Colorado as ever. The present-day prospector is the small lessee in the large and productive camps of the State. It may not be out of order to suggest to the committee that in selecting and outfitting these parties a small assay outfit and assayer with some knowledge of minerals should be provided for each party.

Affairs at the State School of Mines are undergoing the annual shake-up. Complaint comes from many quarters that the president of that institution is too active in politics. To anyone familiar with the political situation in Colorado such criticism seems unjust. The success of the school depends largely upon the funds available for equipment and teaching staff. With so many other State institutions, each strenuously urging before the legislature an increase in its particular appropriation, it would be folly for those representing the School of Mines to keep out of the political game. It is to be regretted that this necessity exists. There will be several changes on the faculty of the institution for the ensuing year. Arthur J. Hoskin and Alwyn C. Smith, members of the mining department, have resigned, and also C. E. Smith, assistant professor of mineralogy. Their successors have not yet been chosen.

The Bureau of Mines rescue car, which has been training men in the use of the rescue apparatus in the coal mines in Wyoming, Colorado, and New Mexico, made a short stay in Cripple Creek early in April. As a result, a mine-rescue association has been formed in the district, and two rescue stations are to be built. These stations are to be fully equipped with oxygen helmets, pulmometers, and storage-tanks. The mines in this district need this apparatus more than the usual metal mines on account of the gases given off in some of the mines when the barometer is low. The Deep Drainage tunnel is somewhat of a disappointment to the more optimistic in the camp. The 6000 gallons per minute which is steadily pouring from the tunnel is lowering the water in the southwestern portion of the camp about as fast as the development work needs to be advanced. The mine owners around Victor and Goldfield, however, are becoming impatient, and the directors at first asked for $40,000 to drive the main heading 2000 ft. farther, but nothing will be done at present. The effect of the drainage tunnel, the success of the local mills, and the low treatment-charges at Colorado City are all evidenced by the increased production. For May the production was 79,160 tons, with a gross bullion value of $1,453,437.

LONDON

WAIHI GOLD MINE.—PRODUCTION FOR YEAR.—PROGRESS ON POWER PLANT.—THE ELMORE PROCESS AT BROKEN HILL.—RESULTS OF WORK.—CHANGE OF POLICY.

The agitation against the directors and engineers of the Waihi Gold Mine, New Zealand, has collapsed. Briefly, the position is that the ninth level is not developing well, and shareholders and speculators are alike anxious as to the future. As is usual when calamitous times arrive, irresponsible people indulge in wild vituperation against anybody and everybody connected with the management and administration. In this case such accusations are baseless and the only legitimate ground for a disagreement from the policy of the board is in connection with the disinclination to commission a mining geologist to make a scientific examination. A perusal of the report for the year 1910 affords a calm opportunity for seeing how things stand. During the year 442,020 short dry tons was sent to the three mills, where by amalgamation, cyanidation, and concentration, 182,693 oz. gold and 1,339,707 oz. silver were produced, yielding an income of £926,099. The assay value of the ore treated was 9.3 dwt. gold and 3.8 oz. silver per ton, and was worth about 6s. 5d. per ton less than that treated in 1909, when 416,813 tons was milled. The tube-mill efficiency has been improved and coarser screens used in the stamps. The daily duty per stamp has been increased from 4½ tons in 1909 to 5 tons in 1910. Out of the total of 330 stamps an average of 295 were employed. The batteries are not worked on Sundays. The profit for the year was £559,191, out of which £396,725 has been paid as dividend, being at the rate of 80%. This compares with £446,316 or 90% in 1909, and £421,520 or 85% in 1908, and is identical with the distribution for 1907. Since 1893 the dividends have totalled £3,957,836. After much consultation with the engineers, the directors determined to maintain the present rate of output until the end of June 1911, and then to reduce it to 1000 tons per day. With the present reserve of ore, this policy will provide work for the mills for two years from now, with the prospect of profits at the rate of 40 or 45%. In the meantime development work is to be conducted vigorously at depth. Progress with the new Hora-Hora hydro-electric scheme is well ahead. The water-channel has been excavated and the foundations of the power-house built. There will be six turbines, each rated at 1500 hp., and the current will be transmitted at 50,000 volts over the distance of 49 miles. The directors naturally felt some misgivings as to the advisability of completing this work, after the position at the mine became uncertain. They decided, however, that it was best, as the mine, though at an anxious period of its life, is by no means moribund, to go ahead with the construction, and they are providing the expense out of the reserve fund, so as not to interfere with dividends. At the meeting of shareholders held this week the directors maintained the dignified and straightforward attitude that has always characterized their doings and showed that they never have had any direct or indirect interest in the ups and downs of the share market. Nothing was heard at the meeting of the opposition proposals to remove the office to New Zealand or to appoint lawyers to the board. But the chairman and shareholders were quite disinclined to spend money on a scientific examination of the geology of the district in its relation to the ore deposits.

In a recent letter I wrote at length with regard to the commencement of a campaign in America by the Minerals Separation company which is now introducing its flotation process to the notice of American engineers. I mentioned also that it had captured the Zinc Corporation of Broken Hill on the strength of an old agreement made years before the processes were perfected, and that the Elmore plant is being put out of employment in favor of the Minerals Separation plant. A good deal of misapprehension may arise through this suspension of the Elmore plant, and, in justice to the Elmore people, it is only right to give official figures relating to the excellent results that were obtained. During 1910, 270,637 tons of zinc tailing was treated; of this, 185,917 tons came from the Block 10 dump, 73,223 tons from the British Broken Hill dump, and 11,482 tons from the South Silver. The concentrate obtained assayed 43% zinc, 10.6% lead, and 14 oz. silver. This was re-treated on Wilfleys, and the commercial products were 85,625 tons of zinc concentrate assaying 46.7% zinc, 5.4% lead, and 11.4 oz. silver, and 9319 tons of lead concentrate assaying 56⅔% lead, 16% zinc, and 38⅓ oz. silver. These results refer entirely to the Elmore plant; no figures were available at the time of the report for the performance of the substituted plant. The income from sale of concentrates during 1910 was £324,040, and the profit was £97,906, out of which £89,513 was distributed as dividend at the rate of 50% on the preference shares. For the previous year the preference shares received 25%. They are entitled to 100% dividend before the ordinary shareholders get anything. It will be seen, therefore, that the profits were excellent, and the directors must feel mortified at having to throw out a successful plant. Recently the Zinc Corporation proceeded to acquire a mine, instead of depending on residues from other people's operations. The Broken Hill South Blocks mine has been purchased for shares. This mine contains a lode that is different in tenor from the main lodes of the district, in that it is higher in zinc than lead. Indeed, the assays show a relative proportion of zinc and lead similar to that in the zinc tailing now being treated by flotation.

WASHINGTON, D. C.

SENATE AND HOUSE MINES COMMITTEES.—FIRST-AID CONVENTION.—POWER-PLANT PROJECT.—INVESTIGATION OF THE STEEL TRUST.—ADJUSTMENT OF CONFLICTS.

The new committees of the Senate and House on Mines and Mining were only recently completed by the Republicans in the House naming the minority members. In the Senate, William Lorimer, of Illinois, was selected as chairman of the committee. The present indications are that another chairman will have to be selected soon, as the old charges against Lorimer are being renewed. It is understood that a number of the men who supported him in the old Congress are beginning to weaken under the pressure of public sentiment and that Lorimer must go. The other members of the Senate committee are: Weldon B. Heyburn, Idaho; George S. Nixon, Nevada; George Sutherland, Utah; Simon Guggenheim, Colorado; Miles Poindexter, Washington; Benjamin R. Tillman, South Carolina; Joseph F. Johnston, Alabama; Clarence W. Watson, West Virginia, and Henry L. Myers, Montana.

The House committee has as the chairman of its Mines and Mining committee, Martin D. Foster, a member who

is well liked, able, and takes an interest in mining matters. The other members of the committee are: William B. Wilson, Pennsylvania; Edward T. Taylor, Colorado; Ralph W. Moss, Indiana; George White, Ohio; W. J. Fields, Kentucky; Curtis H. Gregg, Pennsylvania; James A. Daugherty, Missouri; Adam B. Littlepage, West Virginia; Joseph Howell, Utah; Charles N. Pray, Montana; C. Bascom Slemp, Virginia; Robert M. Switzer, Ohio; Charles C. Bowman, Pennsylvania; and Ralph H. Cameron, Arizona.

The Bureau of Mines, with the coöperation of the Pittsburg Coal Operators Association, is planning a national first aid to the injured meet to be held in Pittsburg sometime in September. It has been proposed to invite every first-aid corps of miners in the United States to compete, showing their skill in this important work. The miners take kindly to the instruction as given by the trained miners on the various rescue cars and quite a number of places now have their first-aid corps.

The Lehigh Coal & Navigation Co. proposes to spend $3,000,000 at once in a plant at one of its mines in Pennsylvania, using the waste culm for fuel under the boilers of steam-engines. If successful, and there is no reason to believe it will not be, the company will ultimately extend its plant until $10,000,000 has been invested. It is hinted that not only the factories and cement-mills in the immediate locality will be served with power, but that the long-distance transmission wires will reach into Philadelphia and supply that great city. The culm piles near the proposed central power plant have more than 2,000,000 tons of fuel. It is believed that this plant is but the beginning of a practical utilization of waste fuel. There is no reason why plants cannot be established in the Middle West, using the low-grade bituminous coal direct from the mines, or in the lignite territory of the Northwestern States.

The new Democratic Congress has appointed a committee to investigate the United States Steel Corporation. The Bureau of Corporations has just completed an investigation of the great steel company, and its report is in the hands of President Taft. The results will be handed to the Congressional committee within a day or two.

Frank Mondell, of Wyoming, former chairman of the Public Lands. Committee of the House, has introduced a bill to provide for the adjustment of conflicts between placer and lode locators of phosphate lands. The bill reads: "That in case of any conflict between locators under the placer laws and the mineral-lode laws on locations heretofore made of lands containing valuable deposits of phosphate or phosphate rock, the respective claims of the locators shall be determined as though location of said lands under either of the above laws was valid at the time said locations were made." Miles Poindexter, new Senator from Washington, introduced a bill to authorize mineral entries on lands of the Spokane Indian Reservation, classified and reserved as timber lands.

NEW YORK

Investigation of Steel Transactions.—Miami-Inspiration Consolidation.—Situation at Porcupine.—Foreign Listing of American Securities.—A. S. & R. Co. Dividends.—Reorganizations.

Not many months ago something was said in this column concerning those banking interests which took credit for averting disastrous panics, but at the same time took as salvage some choice bits of cargo from those institutions that found themselves hard aground on a lee shore. One much-criticized transaction of this kind was the 'benevolent assimilation' of the Tennessee Coal & Iron Co. by the Morgan interests, to be later turned over to the United States Steel Corporation. John W. Gates has recently been before the Stanley Committee at Washington to testify as to this deal. It is rather expected that various New York bankers will be called later, and further light sought on the transactions which were jammed through during the strenuous days of 1907 when the depositors stood in double lines extending around three sides of a city block, waiting while paying tellers behind bank and trust companies' counters fought for time, and paid checks only after every possible delay had been interposed.

The situation at Porcupine is in large part unchanged. The most striking feature is the hostility of the big market and of the press. The New York newspapers will not talk about Porcupine. The endorsement of such men as J. Malcolm Maclaren, who recently came over for Bewick-Moreing, or of Walter Harvey Weed, seems of no avail. When railroad connection is completed, there will probably be a rush that cannot be ignored.

The Mines Company of America, which controls the old Creston Colorada at Minas Prietas in Sonora, Mexico, the El Rayo and the Dolores, both in Chihuahua, and the La Dicha in Sonora, has been listed on the London Stock Exchange. The preferred and common stock issues of the A. S. & R. Co. have also been officially listed in London. The Guggenheim companies are just declaring their regular quarterly dividends. There is quite a little harmless exaggeration in these disbursements, as some of the funds are handled three times before reaching a shareholder. A holder of Guggenheim Exploration gets revenue from Nevada Consolidated only when it is paid out as a dividend for the third time. First by the Nevada Con. to Utah Copper, by that company to the Exploration company, and by the latter to the stockholder.

The Black Mountain Mining Co., a reorganization of the old Nogales Copper Co., is defendant in a foreclosure suit brought by a security-holders' committee representing bonds to the amount of about $170,000. The company is chiefly owned by Chicago interests connected with the Chicago & Northwestern railway, and by Green Bay, Wisconsin, people engaged in the pulp and paper trade. The stock has been traded in Boston for some years. The reorganization committee of the United Rico Mines Co. is having trouble in getting its plans adopted. The company was at one time sponsored by an international banking house of New York, members of the New York Stock Exchange. The committee has been able to secure deposits of stock, but is unable to get the necessary cash for prospecting, development, and working capital. The stockholders are now asked to consent that the money on hand be spent in doing prospecting work.

TORONTO, CANADA

The Fire at Porcupine.—Reconstruction Work.—Progress Reports from Porcupine Properties.—Railroad Extension.

On May 20 a bush fire, fanned by a strong wind, destroyed the mine buildings of the Hollinger, McIntyre, and Pearl Lake mines, and damaged other properties. The loss was at first estimated at from $300,000 to $500,000, but later reports are to the effect that it will not exceed $150,000. The Hollinger sustained the principal damage, as nearly all the machinery, excepting the heavier parts, was destroyed and the shaft-houses were burned, the men underground escaping with difficulty. Immediate steps will be taken for the reconstruction of the plant, which may necessitate the building of miles of road to enable the getting in of heavy machinery and material. All underground work will necessarily be suspended in the meantime, and many of the men have been paid off. Shortly before the fire, cross-cutting to the east intersected an orebody 24 ft. wide, yielding an average value of $15 to $18 per ton. The management estimates that there is enough ore blocked out to supply the 30-stamp mill for ten years. At the McIntyre where one power-house and camps were burned, work on the south vein now down 80 ft. will proceed uninterruptedly. New machinery is being purchased for the shaft on the north vein. The Pearl Lake, which lost its office and store-houses and some small buildings, will not be seriously affected. There was a considerable drop in Hollinger and other stocks for a day or two after the fire, but they speedily rallied and at present prices are well maintained, though trading is quiet.

The Scottish-Ontario is driving a cross-cut from No. 1 shaft north 300 ft. to pick up a vein indicated by surface

outcroppings. Several veins have been found in the course of the work. At the Dome the foundation for the stamp-mill has been completed and the building commenced. No. 7 shaft has been made into a double-compartment working shaft to connect with all the workings. The orebody has been tested by drilling to a depth of 700 ft. At the West Dome the compressor house has been finished and the main shaft is down 85 ft., at which level underground work will be carried on. The Preston East Dome has started sinking on two veins and has a large force engaged in trenching and stripping. The Standard is down 60 ft. in No. 2 shaft on a contact between schist and porphyry, following a pay-shoot in the porphyry about 6 ft. wide, stated to average $33 per ton to a depth of 25 ft., when it dipped out of the shaft. A cross-cut will be run at the 100-ft. level to pick it up. A New York syndicate has taken over the Leblanc claims, adjoining the Eldorado Porcupine, which is reported as very rich. It is announced that George E. and T. J. Drummond, of Montreal, have acquired a controlling interest in the Jupiter mines.

The Swastika mine, about twenty miles south of Matheson on the Temiskaming & Northern Ontario railway, has become a shipper. Development has been in progress for three years; a shaft is down 100 ft., a winze 100 ft. below that level, and 1250 ft. of driving and cross-cutting. A five-stamp mill has been for some time in operation and gold to the value of $4400 has been produced. The shaft is to be sunk 500 ft. Trains are now running on the Porcupine branch of the Temiskaming & Northern Ontario railway from Kelso on the main line to Frederickhouse river, a distance of fifteen miles, though subject to frequent delays and uncertainties, owing to the unfinished condition of the track. As a rule travelers prefer to walk. The remainder of the journey can be accomplished by water.

GOLDFIELD CONSOLIDATED MILL.

GOLDFIELD, NEVADA

MAY OPERATIONS OF THE GOLDFIELD CONSOLIDATED.—JUMBO EXTENSION DEVELOPMENT.—THE FLORENCE GOLDFIELD.

Preliminary estimates of the May production of the Goldfield Consolidated Mines Co., just issued by the general superintendent, place the gross recovery from 29,410 dry tons of ore milled at $882,000, an average of close to $30 per ton; operating costs at $215,000, and net profits at $667,000. This is the largest tonnage mined and treated during any month in the history of the company, although the average grade of ore for May was lower than that of the previous two months. The mill treated an average of 949 tons daily, an increase of considerably more than 100 tons per day over the average of last year. The bullion shipment of nine bars last week was valued at $310,000. It is reported that an important ore discovery has been made on the 600-ft. level, at a point between the Clermont and Laguna shafts and, from its position, may be the downward extension of the rich orebody opened in the Bulldog Fraction, purchased a short time ago from the Red Top Extension Co., after the vein had been exposed by lessees. This vein is a part of the Red Top ore channel and has its apex on Consolidated ground. There is said to be an improvement on the 1200-ft. level of the Grizzly Bear workings, where the quartz mass, as stated in the last report of the superintendent, has greater width than on the 1000-ft. level of the Clermont. Results of development on the 900-ft. level of the Clermont are reported to be satisfactory; and the $200 ore reported in the Combination mine is said to be holding out.

Development work on a large scale is to be carried on by the Jumbo Extension Mining Co. In this work the company has the advantage of beginning at a depth of 1030 ft. and has the use of a good plant. The work will be conducted on the Polverde claim, adjoining the Clermont and Laguna of the Consolidated, and the St. Ives and Velvet claims of the Goldfield Merger Mines Co. All of the surrounding claims have produced ore of high grade, and the Polverde itself has been producing ore of shipping grade for the greater part of a year from the Annex lease, covering the central part of the claim. The lessees have exposed ore on the 760, 800, and 850-ft. levels and have explored to the southern boundary of their territory on the 1030-ft. level. A station has just been completed on the 600-ft. level, where the shaft cut the vein. The Jumbo Extension company will continue driving the southern cross-cut on the 1030-ft. level from the Annex shaft, the work to be under direction of Walter S. Norris. The directors of this company last week declared a dividend of 10c., to be paid July 15 to stockholders of record July 1. Of the 1,250,000 shares, constituting the company's capital stock, 971,657 shares have been issued. After the forthcoming dividend is paid the treasury will contain a cash balance in excess of $100,000.

A discovery of good-grade ore has been made on the 500-ft. level of the Florence Goldfield mine at a point between the main shaft and the old workings of the Engineer's lease. High-grade ore is now being broken from this ore-shoot in which drifts are being extended north and south. The main shaft has reached a depth of 900 ft., at the bottom of which station No. 10 will be cut, making the tenth level the main working level below the 500-ft. Laterals are to be extended north, east, and south from this station to explore the downward extension of several ore-shoots from which the company and the early lessees have extracted high-grade ore on upper levels.

General Mining News

ALASKA

Ketchikan District

The Victor Copper Co., whose work on Gravina island is in charge of Patrick Heaney, has driven a cross-cut over 2000 ft., whereby several veins of chalcopyrite ore have been interseeted at great depth. Driving is to be continued some distance farther to cut other veins before stoping and shipping are begun. James W. Malcolmson and M. McTernan, of Kansas City, stockholders in the company, inspected the property last month. The principal supply point is Ketchikan.

Prince William Sound

William Morris has purchased a controlling interest in the Brooks-Hardenburg copper property in the vicinity of Iliamna, on the west side of Cook inlet. Mr. Morris is said to represent some of the large copper operators in the States.

Seward Peninsula

The steamships *Victoria* and *Senator* sailed from Seattle for Nome the first week in June, both loaded to full capacity with passengers and freight. It is expected the former will be the first of the larger boats to lead the way through the ice floes of Bering Sea this season.

The Tanana

(Special Correspondence.)—W. F. Copeland, representing the Guggenheims, has opened offices in Fairbanks and has a Keystone drill ready for work on lower Fairbanks creek, to prove the ground tied up on options by Falcon Joslin last year. The prospect is that dredges may be operated there. The Fairbanks Quartz Development Co. has taken a 15-year lease on the Butler-Petree and Rex properties, on Chatham creek. It is the intention of the company to develop the property this season. It has a good surface showing. The directors of the company are J. R. Mathews, Tony Nordale, E. R. Peoples, Martin Harrais, and R. C. Wood. Stock in the Fairbanks Core Drill & Mining Co. is now being subscribed for by local people, and the intention is to have one Davis Calyx drill that will extract a 3-in. core to a depth of 800 feet.

While most placer areas are speedily worked out, those of the Fairbanks district seem to persist with new finds every year. A summary of placer work last winter shows new pay on several creeks. Besides the new paystreak found on the left limits of both Fairbanks and Goldstream, Eva, Fish, and Ester creeks will be producers. Probably the biggest producers will be the Niggerhead and Alabama associations at the mouth of Dome creek, with the left limit pay on Goldstream a close second. Rich ground is also being prospected by Jim Lashbaugh on Engineer creek.

Fairbanks, May 25.

ARIZONA

Cochise County

The lessees working in the mines of the Tombstone Con. Mines Co. are making regular shipments of ore to the Douglas and El Paso smelters. The Great Western M. Co., operating in Courtland camp, is shipping one car of ore per day to the Douglas smelter.

Greenlee County

The 1910 production of the mines of this county, according to data supplied the county assessor, aggregates $9,262,202, distributed as follows among the mines of the Clifton-Morenci district: Shannon Copper Co., 15,873,481 lb. copper, 984.47 oz. gold, 47,726 oz. silver, valued at $2,067,735; Arizona Copper Co., 33,391,530 lb. copper, valued at $4,253,413; Clifton Copper Co., 206,419 lb. copper, value, $26,293; Detroit Copper Co., 22,546,201 lb. copper, valued at $2,871,935; Standard Consolidated, 50,582 lb. copper, 3347 oz. silver, valued at $8235; Standard Copper mines, 270,540 lb. copper, value, $34,461. The Shannon and Arizona Copper companies both increased their output for 1910 over that of 1909. The April production of the A. C. Co. was 2,840,000 lb. of copper.

Mohave County

The Frisco Mines & Power Co., the property of which is at Union Pass, is mining and milling ore having an average value of $12 per ton. A recent mill-run of 100 tons showed an average of about $20 per ton. The principal metal of value is gold, and the mine workings expose a big tonnage of ore in a wide vein. This camp is about 25 miles west of Kingman.

The Bi-Metal mine and mill, 3 miles from Kingman, were inspected last week by mining men from Denver, with the idea of resuming operations if, on examination, the conditions appear to justify doing so. The property has been

MORENCI, ARIZONA.

idle since last year. The property comprises 100 acres of mineral ground on the Santa Fé railroad, where the formation is granite-porphyry, with intrusions of diorite, through all of which some free gold is disseminated. It belongs to the Arizona Gold Mines Co., in which E. M. Lamont, of Denver, was managing director. The last week's run of the Gold Road mill resulted in a clean-up of $17,000. The tonnage of ore treated during that week was smaller than usual.

Pima County

The Helvetia Copper Co., having an area of about 800 acres of mineral land at Helvetia, in Santa Rita mountains, 30 miles south of Tucson, has ceased operations because of the lack of funds to pay further expenses. It is said, however, that the company has no debts. The mine development has exposed a big tonnage of copper ore, both carbonate and sulphide, running 2 to 3%, but as the mine is 20 miles from the railroad, expenses of operating are high, leaving no profit. The smelting plant contains a 100-ton copper furnace. The heaviest production was during 1906 and 1907.

The Cerro Colorado mining property, 4 miles west of Arivaca, is being equipped with a 150-hp. steam boiler, a double-drum hoist, cages, air-compressor, and drills, F. J. Snyder being in charge. Assays of one lot of samples of the ore by E. A. Jacobs, of Tucson, are said to have shown 24% copper and 58 oz. silver; another lot assayed 12% copper and 156 oz. silver.

Pinal County

The Magma Copper Co., which is developing its Queen mine, at Superior, has finished the work of sinking the 2-compartment shaft to a depth of 800 ft. A cross-cut, being driven from the side of the hill, is to be connected with the shaft at 280 ft. below the collar of the latter. A good-sized station is to be cut at this connecting point, where a hoist will be put in position, making this the principal hoisting station for ore and waste, which are to be hauled out to the surface through the cross-cut. The fissure vein has been opened by cross-cuts driven from the 300, 400, and 650-ft. stations, whereby it was demonstrated that the vein is about 8 ft. wide, the ore assaying high in copper and silver. A similar cross-cut is now being driven to the ore from the 800-ft. station. This camp is about 30 miles north of Florence.

A proposal to consolidate the interests of the Ray Con-

tral and Arizona-Hercules, at Ray, is being considered by those concerned. The Ray Central holdings lie on the west side of Mineral creek and north of the Ray Con. group; while the Arizona-Hercules holdings of 240 acres lie on the east side of Mineral creek, extending about 3900 ft. along both sides of the Ray fault, or contact of diabase and schist. The Ray Central is developed from a vertical shaft, and the Arizona-Hercules has been thoroughly prospected by churn-drill holes. The former is controlled by stockholders represented by J. B. Cummins; the latter is owned by W. P. Dunham and associates. Both are within the zone of copper-bearing Pinal schist, in which the Ray Con. has developed great ore reserves.

Yavapai County

The Gray Eagle and Cleveland mines, in the Bradshaw mountains, near Crown King, have passed to the Tiger Gold Co., for $60,000, the last payment of $5000 having been made recently to P. Kearney for his interest in the property.

W. C. Clark, manager for the United Verde Copper Co., operating the mine and smelter of that name at Jerome, recently visited most of the smelting plants in Arizona, and is reported as having stated that a new smelter probably would be built at the United Verde mine. The plant now in use, while it has been altered and enlarged some in the last 10 years, was originally built about 16 years ago.

CALIFORNIA

Amador County

(Special Correspondence.) — The Kennedy shaft has reached the depth of 3550 ft., including a 100-ft. sump. The shaft is expected to cut through the hanging-wall vein at a depth of 3800 to 3900 ft., and the foot-wall vein at about 500 ft. deeper. The lowest working level at present is the 3450-ft.; from the 2300 to the 3450-ft. levels the orebodies range from 5 to 12 ft. wide, the ore being of milling grade throughout. North of the shaft the shoots are about 500 ft. long, while to the south they have a length of 700 ft. On the bottom level the vein is 15 ft. wide. In addition to the usual grade of ore mined and milled, there are in places small bodies of high-grade quartz, assaying $1000 per ton, the management guarding this closely at all times. Ore for the 100-stamp mill is being taken from ten levels, and 500 tons per 24 hours are crushed. From the mortars the ore passes to amalgamating plates, thence to forty 6-ft. vanners. The tailing is treated on canvas tables, and the concentrate is treated by the chlorination process, the company having its own plant for this purpose. About 92% of the assay-value of the ore is recovered at a cost of $5.50 per ton. Approximately 350 men are employed. The company pays monthly dividends, ranging from 15 to 30 cents per share. Webb Smith is superintendent. It is reported that a 4-ft. vein of ore assaying $22 per ton has been opened on the 800-ft. level of the Lincoln Consolidated. The discovery was made in the south drift. Developments will be conducted from the next lower level to prove the extent of the discovery. The mine was formerly a noted producer. South Eureka orebodies are reported to be showing up favorably. The mill is running at full capacity. It is reported that persons representing Eastern interests are about to resume work at the Plymouth Consolidated.

Jackson, June 5.

Inyo County

The Estella Mining Co., having a group of claims on Cerro Gordo mountain, 4 miles from Keeler, began two years ago to drive the Troeger cross-cut to tap at great depth the Morning Star vein in which high-grade ore had been mined near the surface. This cross-cut now has a length of 4000 ft., and in the vicinity of the present heading a vein was intersected which is said to contain 12 ft. of tetrahedrite ore, samples of which assay about $200 per ton. The place where the vein was discovered is 2000 ft. vertically below the surface. The cross-cut is to be extended to the vein for which it was started. At the portal of the tunnel is an air-compressor, driven by a gasoline engine. By other development this company has placed 200,000 tons of ore on the dumps. R. C. Troeger is manager for the company.

Mariposa County

The Oro Rico Mines Co. has just purchased of the Joshua Hendy Iron Works the complete equipment for a 20-stamp mill, including amalgamating plates and Deister concentrating tables.

Merced County

The Yosemite Dredging & Mining Co. is operating a dredge with 3½-cu. ft. buckets, on the Merced river, the operating headquarters being at Snelling. James W. Neill of Pasadena is one of the directors.

Placer County

(Special Correspondence.)—The Pioneer mine, situated near Towle, is an old property, comprising 17 patented and 8 unpatented lode claims, containing two parallel veins, about 900 ft. apart, each having a dip of about 65°, and lying between greenstone and slate. Both veins have been opened to a depth of 1100 ft. by a 2600-ft. cross-cut, which is used as the main working-level. Drifts on the veins, at this level, aggregate about 2500 ft. The width of the veins varies from 4 to 70 ft., the gangue material consisting of quartz and argillite, containing gold that occurs free and associated with arseno-pyrite. The property is equipped with a mill, having four 5-stamp batteries of 900-lb. stamps, amalgamating plates, and Frue vanners, in which about 80 tons of ore per day is being treated. Of the saving made, close to 80% is recovered on the plates, and 20% in the concentrate. The average value of the ore milled is close to $10 per ton. The mill machinery and air-compressor are driven by water-wheels under pressure of water from the American river. The property is now owned by the Consolidated Pioneer Gold Mines Co., by which it has been operated during the last year, and for which H. W. Morris is superintendent.

The Helen-Esther M. Co., which is operating what was formerly known as the Rawhide mine, two miles north of the Pioneer, and on the same vein system, is adding 30 stamps to its 10-stamp mill. This company, for which J. L. Bryson is manager, purchased the property two years ago. The former operators are said to have milled 40,000 tons of this ore, which averaged $5 per ton. The Helen-Esther company is made up of Massachusetts people.

Towle, June 3.

The El Dorado-Placer Gold Dredging Co. is operating a dredge of the Risdon type, with 3½-cu. ft. buckets, on the middle fork of American river, the work being in charge of Charles H. Schooler. The ground being dredged is in the deep canyon of the river, the walls on both sides rising to a height of 3000 to 4000 ft. The equipment and material for building the dredge had to be lowered from the top of the cliff to the bed of the stream by means of a surface tramway provided with winding machinery. The work is in the vicinity of Newcastle.

Shasta County

The Little Nellie mine, in the vicinity of the Iron Mountain mine of the Mountain Copper Co., near Keswick, has been equipped with a 10-stamp mill, which is now in operation, in charge of A. B. McVay. The ore being treated is said to run about $17 per ton.

Siskiyou County

A. B. Dodd and S. J. Silva are operating the Mono mine, situated near Yreka, under an option to purchase it. The work is in charge of G. Winwood. J. Salisbury has leased the Hazel mine, near Hornbrook. The water is being pumped out of the shaft, and the timbering is being repaired.

Gold nuggets and fine particles of gold of the value of $1400 were extracted last week from the Little Bonanza mine, in the vicinity of Hawkinsville, by Newton Gordon, owner of the property.

Tuolumne County

(Special Correspondence.)—Operations are to be commenced at the New Era mine by A. C. Redding and W. F.

Russell, to whom the property was recently bonded by W. T. Carter. A body of good-grade ore was uncovered a few days ago on the 1150-ft. level of the Harvard mine. At the Helm-Hiatt mine, near Deer creek, an adit is being driven to tap the vein far below the old workings. With only an arrastre to crush the ore, the property was worked with fair success a number of years ago. The Tappie mine, situated between Rawhide and Tuttletown, has been bonded to Albert Morgan and Walter Talbert, and preparations are under way for the operation of the property. Repairs are being made to the mill, and a building to be occupied by the employes is being erected. The milling of 220 tons of ore from a 6-ft. vein at the Chileno mine, on Jackass hill, operated by C. A. Gillis, gave returns of $5 per ton in free gold, in addition to which 24 tons of concentrate was saved which yielded $20 per ton. The crushing plant on the property is unsatisfactory and a new one will probably be constructed. The Berkeley Mining Co., which recently brought suit against the owners of the Ida Klein mine to recover money paid on the purchase price of the property, alleging that fraud had been practised, is the defendant in an action instituted on May 31 by A. A. Jacobs, who seeks to force the mining corporation to pay $1238. Of this sum $814.25 is said to be due for supplies furnished by plaintiff, the balance representing two assigned claims, one of $227.16 from the Jamestown Lumber Co., and the other of $196.69 from W. E. Booker.

Tuolumne, June 3.

COLORADO

Clear Creek County

(Special Correspondence.)—The Lucania adit, on Bellevue mountain, is being driven at the rate of 200 ft. per month. An 8-in. streak of gray copper ore has been uncovered on the third level of the Lombard mine, assaying $300 to $500 per ton in silver and gold. Chalcopyrite has been found at the bottom of the 60-ft. shaft, on the Empress vein, running $90 per ton in gold and silver. It is stated that work will be resumed in the Honest John adit on Chicago mountain. The bore is now in 2300 ft. Work on the reduction plant that is to be provided with the McKelvey amalgamating process has been commenced. A shipment of 8 tons of smelting ore from the Silver Horn mine sampled 200 oz. silver and 2 oz. gold per ton. E. Hunter is manager. N. J. Pike & Co., leasing on the Old Town mine, sent out a carload of smelting ore last week, gross returns for which were 5.70 oz. gold, 10.20 oz. silver per ton, and 4.10% lead.

Idaho Springs, May 19.

(Special Correspondence.)—A. Erickson, leasing on the third level of the Seven-Thirty mine, has started a drift on an 8-in. streak of gray copper ore that samples 395 oz. silver per ton. The 50-ton mill at the Conqueror mine, Covode mountain, was started last week. George Schneider, the manager, states that work on the new 200-ton mill will be started at once. J. L. Cutting has a contract to drive 500 ft. on the Clinton vein, in Daily district. S. A. Offerson, leasing on the Gold Dirt mine, is stoping on a body of smelting ore 18 in. wide, that assays $70 per ton in gold. Ore is being shipped to the Golden smelter. A body of steel galena 2 ft. wide has been uncovered in the 300-ft. raise driven from the adit on the Aetna vein at the Capital mines. A shipment made shows the ore to be worth $120 per ton in gold, silver, and lead. A road is being constructed from the flat on Alpine mountain to the Sporting Times mine.

Georgetown, May 28.

Gilpin County

(Special Correspondence.)—The London claims, in Twelve Mile district, have been taken under bond and lease by A. T. Holman, representing a syndicate of Michigan investors. There is a 100-ft. shaft, with some drifting on the vein. The Moon Anchor mine will be an ore-shipper this summer. It contains a 3-ft. vein of smelting ore on which a drift is being advanced. The ore samples $40 per ton in gold. P. Fransen is manager. Stephens & Co., leasing on the 600-ft. level of the Topeka mine, are shipping mill ore that has a value of $10 per ton. The smelting ore samples $25 per ton. A shipment of 20 tons of smelting ore from the Federal mine, made by R. Hughes, brought a settlement of $51.38 per ton in gold and silver. Operations are on the 400-ft. level.

Central City, May 29.

Lake County (Leadville)

Burton, White & Co., lessees on the Chrysolite mine, have developed a body of zinc carbonate, 12 ft. wide in some places, the ore in which is about 36% zinc. The property is a regular shipper. The Western Mining Co., S. D. Nicholson, manager, is operating the Wolftone, Maid of Erin, and other mines on Carbonate hill, and shipping zinc ore.

Teller County (Cripple Creek)

The ore output of the mines in Cripple Creek district during May amounted to 79,160 tons, of an average grade of $18.35 per ton, the total value of bullion extracted being

GOLDEN CYCLE MINE, CRIPPLE CREEK DISTRICT.

$1,453,437. The tonnage and value of ore treated at the six principal mills, which run on Cripple Creek ore, together with that sent to smelters, are given as follows:

Plant.	Tons.	Average Value.	Gross.
Golden Cycle	29,070	$20.50	$595,935.00
U. S. R. & R.	14,165	22.00	311,630.00
Portland	10,000	20.00	200,000.00
Portland, Victor	10,075	3.57	35,967.75
Stratton (Est.)	10,600	3.10	32,600.00
Wild Horse	1,050	4.10	4,305.00
Smelters	4,200	65.00	273,000.00
Totals	79,160	$18.35	$1,453,437.75

It will be noted that only the highest-grade ore was shipped to the smelters; that the mill ore grading from $20 to $22 per ton was shipped to the big mills at Colorado City, while over 21,000 tons of ore sampling from $3.10 to $4.10 per ton was treated at the Portland, Stratton, and Wild Horse plants in the district. The Western Reduction Co., operating a mill at the Isabella mine, has commenced work, and will doubtless make a report of June business.

The Elkton Con. M. & M. Co. is sinking its main shaft as rapidly as the water-level is lowered as the result of the drainage through the Roosevelt tunnel, the bottom of the shaft being now below the 900-ft. station. A winze has been sunk 60 ft. below the 900-ft. level in ore that assays about $40 per ton. The ore below this level, without sorting, is said to average $35 per ton. Henry Von Phul and associates are shipping ore taken from the Fair Chance ground, on the western slope of Beacon hill. Their ore is mined in a 3-ft. vein, samples of which assay $15 to $40 per ton. George Diamond and Charles Walker have a 2-years lease on a block of the Coriolanus mine, on Battle and Squaw mountains, expecting to operate through the Columbine-Victor lateral, by which this property is tapped at 600-ft. depth. Charles Stream and Charles Erne have a similar lease on another block of Coriolanus ground. The royalties to be paid by lessees will vary according to the grade of the ore. This property belongs to T. B. Burbridge.

D. H. Curry, lessee on the Monument mine, near Victor, is mining ore running about 2 oz. gold per ton from the 500, 400, and 500-ft. levels, and is shipping 3 to 4 cars per week. The Rubie Mining & Leasing Co. has its lease renewed on the Rubie and Lafayette mines, on Bull hill. These mines belong to the Princess Alice G. M. Co., and the lease continues till January 10, 1914. The leasing company is shipping 100 tons per week of ore assaying 2 oz. gold per ton. It pays royalties graded from 10 to 25%. The Ajax mill, being built on Battle mountain, probably will be ready for work in July. The equipment provides for the Clancy method of cyanidation, in which the Moore filters perform a part. The Cavanaugh cyanide plant, being erected at the Jo Dandy mine, Raven hill, is soon to be ready to treat ore. The Jerry Johnson, Forest Queen, and W. P. H. mines, situated on Ironclad hill, all in the hands of lessees, are regular ore shippers, 5 cars having been sent out on May 30. Shipments of two cars were made on the same date from the Deerhorn mine, Globe hill, belonging to the Stratton estate, and under lease to William Fitts.

It is announced that the directors of the drainage company have decided not to undertake the extension of the Roosevelt tunnel at present. The average subsidence of water in the district since the water channels were tapped by the tunnel is said to be about 36 ft., or not more than 6 ft. per month, which is much slower than was anticipated. One estimate places the volume of water in the district basin at 40,000,000 gal. per vertical foot. The outflow through the tunnel is 6000 gal. per minute.

IDAHO

Blaine County

The Blaine Mining Co. is to re-open and work the Solid Muldoon mines, at Tustin, in the Wood river country. Samuel and David E. Crawford, of Michigan, and E. C. Eastman, of Wisconsin, are principals in the company, and H. J. Allen of Hailey is to have charge of the work.

The Boulder Con. M. Co., composed of William Schultz, of Hailey, M. W. Wood and L. J. Falk, of Boise, and others, has driven an 800-ft. cross-cut on a group of claims, 25 miles north of Hailey, by which two veins of ore have been opened, and from these some high-grade ore has been extracted and sold. The group is on Boulder creek, at the base of the Sawtooth range. The cross-cut is to be extended, and if continued to a point below the crest of the range, as contemplated, it will have attained a depth of 3800 ft. Mr. Schultz located the claims 31 years ago.

Idaho County

The custom mill of the Elk City Reduction Co. is expected to be ready for work by July, and a sufficient tonnage of ore is said to have been pledged to keep the mill running the rest of the summer. Most of the ore mined in this locality is incidental to development work. The Elk City Mines Corporation, which operates the South Fork mine and mill, near Elk City, cleaned up gold bullion valued at $3500 as the result of 12½ days run of a 5-stamp mill. Operations are to be continued.

Shoshone County

(Special Correspondence.)—The report for the seven months of the fiscal year ended March 1911, just issued by the Federal company, shows a gain of $347,000 over the corresponding period a year ago, which means there was a surplus of $194,000 after paying charges and dividends on preferred stock, as against a deficit of $153,000 for the same period 12 months ago. The earnings for March were $118,000, an increase of $55,000 over the same month a year ago. As preferred dividends call for $840,000, the company already has earned for the current year within $156,000 of its needs in this respect.

Wallace, June 1.

The Bunker Hill & Sullivan Mining & Concentrating Co., the great mines of which are at Wardner, is reported as having seven years' supply of ore blocked out. The company is operating two concentrating mills and a tailing plant at Kellogg, the two mills treating about 1350 tons of ore per day. The third concentrating plant is being erected, and when it is ready to operate the combined capacity of the three mills will be 4500 tons of ore per month.

MONTANA

Broadwater County

(Special Correspondence.)—The Ohio Keating M. Co., operating in the Radersburg district, has about completed arrangements for building a concentrator for treating its low-grade ore. The company at present is shipping three carloads of ore each week.

Radersburg, June 3.

Silverbow County

(Special Correspondence.)—Although no official information has been given out, there is a report, which seems to be well founded, that the Butte & Superior company will not undertake construction of a concentrator this year, but will continue to ship its ore to the Basin reduction works. Under present conditions the company is getting good results, and it is felt that a large treasury fund should be accumulated before the erection of the mill is undertaken.

Butte, June 3.

NEVADA

Humboldt County

The Gold Ledge M. Co., made up of Kansas City people, has developed its mining claims, situated on Kramer hill, 2 miles south of Goleonda, and has constructed a mill that is to be ready to operate this month. The ore is taken from the mine through an adit-level by which 200-ft. depth on the vein is gained. A winze is also being sunk on the vein from the adit-level. Charles J. Frye, of Kansas City, is manager for the company. The Wanonah Mining Co. is developing a mining property at Gold Run, 12 miles south of Goleonda. A body of ore, opened by a long cross-cut, has proved to be 20 ft. wide, some of the ore therein being of shipping grade. A raise made from the cross-cut to the workings above it has given good ventilation. D. E. Moore is in charge of the property. Work is being performed on the West Dip, Black Diamond, Nevada Crown, and Warren placers, in the same district.

Esmeralda County

(Special Correspondence.)—The estimated production of the Goldfield Con. Mines Co. for May amounted to 29,410 tons of ore. Gross value of metals recovered, $882,000; operating costs, $215,000. Net profit for the month, $667,000. Mines looking well.

Goldfield, June 3.

Lyon County

The Nevada-Douglas group of mines, in Yerington district, comprises the Douglas, with 200,000 tons of ore developed that is estimated to run 3% copper; the Copper Basin, on which close to 50,000 tons is opened, running 4.5%; the Ludwig, in which there is claimed to be developed nearly 600,000 tons of ore, estimated to assay 5.4% copper. A shipment of 1192 tons of ore from the Douglas mine sampled 13.49% copper, 0.01 oz. gold, 0.67 oz. silver, 20.28% iron, 22.72% silica. This company built the Nevada Copper Belt railroad from Wabuska to Douglas, via Mason, a distance of 33 miles, now in operation.

Nye County

(Special Correspondence.)—The control of the Plamenaz lease on Union No. 9 claim has passed from C. B. Putman and James Shea to the Manhattan War Eagle M. & M. Co. for a reported consideration of $20,000. In addition to the cash payment, the purchasers have granted a long-term lease to Putman & Shea on the Jumping Jack. Operations on the latter will be commenced by the lessees. The Jumping Jack is near the Big Four, being separated from it by the Golden Wedge. The Big Four Leasing Co. has its air-compressor and motor in place, and electrical connections are being made. The sinking pump, at the 220-ft. station, soon will be lowered to the 300-ft. level, and driving for the vein will be started at this station.

Manhattan, May 31.

The output of the mines of Tonopah for the week ended

June 3 was as follows: Tonopah M. Co., 3000 tons; Belmont, 2910; Montana-Tonopah, 1045; Tonopah Extension, 980; Midway, 50; West End, 150; total, 8135 tons, of the estimated value of $203,375.

The Bonnie Clare M. Co., for which J. L. Hisey is manager, is starting its 100-ton mill in operation at Bonnie Clare station. The ore supply is being hauled from the mines of this company on Gold mountain, 9 miles away. It is expected that some custom ore will be received from other mines at Gold mountain and Horn Silver. The mill machinery is driven by electric power from the line of the Nevada-California Power Co. The proposal to build a trackless trolley line from Bonnie Clare to Gold mountain, for service in ore haulage, is being considered.

STOREY COUNTY (VIRGINIA CITY)

The Mexican G. & S. M. Co., during the week ended June 3, did some cross-cutting on the 2200-ft. level; and drove the north drift No. 2, from the east cross-cut, 18 ft., extended the south drift 11 ft. on the 2300-ft. level; and started a raise from the south drift, from which 66 mine-cars of ore were taken, averaging $57 per ton. On the 2400-ft. level, the north drift from the west cross-cut off north drift No. 2 was extended 25 ft., and from that drift 108 cars of ore averaging $19.47 per ton were taken; and in the north drift from east cross-cut No. 2, at 366 ft. in, a raise was driven 15 ft. in ore, from which 72 cars of ore, assaying $72.98 per ton, were mined, and in cutting out for a chute 15 cars of porphyry and quartz were taken of an average value of $19.04 per ton; work was done on the first, fourth, and fifth floors of the stope at the end of the north drift on the 2500-ft. level, from which 101 cars of ore were mined, assaying $88.90 per ton, also 6 cars of porphyry sampling $20.65 per ton. During the week there were shipped three railroad cars of first-grade ore to the smelter.

The estimated production for the week of the Mexican, Ophir, and Con. Virginia, known as the north-end mines, aggregated 757 tons, of the value of $32,459. The Mexican produced 368 mine-cars of ore, valued at $21,011; the Ophir's output was 230 tons, worth $9902; that of the Con. Virginia being 159 tons, valued at $1545.

WHITE PINE COUNTY

The Allen mine, under lease to Ed Wilson and Ole Johnson, of Ely, and situated in the Red Hills district, 40 miles northeast of Ely, is a producer of high-grade lead-silver ore. These lessees have hauled 80 tons of the ore 60 miles to Currie station, from which place it was shipped to the smelter.

NEW MEXICO

The gross output of coal mined in New Mexico during the last fiscal year amounted to 3,293,486 tons; coal consumed in operating the mines, 38,533 tons; unwashed slack and coal sent to coke ovens, 802,676 tons; coal shipped to market, 2,433,739 tons; coke marketed, 397,102 tons. Value of coal and coke shipped, $4,693,870, an increase over that of the preceding year of 19.7 per cent.

GRANT COUNTY

The Chino Copper Co. has four 90-ton and one 40-ton steam shovels in operation on its copper properties at Santa Rita; the result of their operations is that 334,000 cu. yd. of overburden has been stripped off the orebodies, and 134,000 tons of copper ore has been accumulated in the stock piles. The first unit of the concentrating mill is expected to be in operation next month.

SOCORRO COUNTY

(Special Correspondence.)—The Maud Mining Co. has its steam-hoist in place for sinking its two-compartment shaft. About 15 men are now employed. The clean-up last week at the Deadwood mines amounted to 2350 oz. gold and silver bullion. The tonnage of ore crushed was 280, with 15 sacks of concentrate. The third drift west of the Socorro mine is still in good ore. This is the level from which a shipment of high-grade ore was made some time ago. The mill is treating 150 tons daily, operating on average-grade ore. The Oaks Company has advanced its tunnel 15 ft. About half of the crew's time is spent in grading a road leading to the site. The portal of the tunnel will be timbered with square-sets as soon as the material can be delivered. An air-compressor is to be provided, to be driven by a gasoline engine.

Mogollon, June 3.

OREGON

JOSEPHINE COUNTY

The smelter of the Almeda Con. Mines Co., situated at Galice, is treating about 100 tons per day, and turning out 10 tons of matte.

UTAH

SALT LAKE COUNTY

(Special Correspondence.)—Utah Copper is making preparations to increase its production. It is probable that the company will increase the output sufficiently to leave a good margin over the $3 annual dividends. The last statement showed that the company was cutting close to the line with its previous rate of production. The regular quarterly dividends of the Utah Copper and Nevada Consolidated have been declared, the former 75c. per share and the latter 37½c. The total of Utah Copper dividend is $1,171,987, bringing the gross amount to date to $9,136,565. Nevada Con. will pay $749,380, bringing its total up to $5,081,371. Both dividends are payable June 30. The annual statement of the Bingham Mines Co., gives the total assets December 31, 1910, as $2,148,676, of which $128,812 is in cash and accounts receivable. Accounts payable are $352, and floating indebtedness $47,439. Capital stock is $945,560, and the balance of the liabilities are in the funded debt. Ohio Copper Co. will hold its annual meeting June 7, at Portland, Maine. It is reported that the gathering will show F. A. Heinze to have surrendered his control. The directors of the Bingham Mines Co. have submitted two plans of reorganization which will be considered at the annual meeting June 21. The present capital is 800,000 shares, par value $1. One plan is to increase the number of shares and issue convertible bonds. Another is to form a new company of 300,000 shares, par value $5, set aside 160,000 shares for exchange of the old stock, and put the balance in the treasury for sale. It is also suggested to make the stock assessable. The directors state that the orebodies already developed justify vigorous development.

Salt Lake, June 1.

WASHINGTON

FERRY COUNTY

(Special Correspondence.)—There was shipped from the mines of Republic district 3700 tons of ore to the smelters during May. It is estimated that over 7000 tons of ore of milling grade was broken and stored, in the meantime, to await the completion of the mill of the North Washington Power & Reduction Company.

The Knob Hill company has received the smelter returns from 3 cars of ore which show as follows: 198,036 lb., assaying 3.62 oz. gold and 7.01 oz. silver per ton. The gross value of the shipment was $7166.94; net returns, $6065.18. Returns from another carload show 1.835 oz. gold and 3.85 oz. silver per ton; dry weight, 91,922 lb.; gross value, $1692.14; net returns, $1177.53. The Knob Hill company declared a dividend May 29 of $10,000. The Quilp M. Co. paid a dividend of $15,000 on May 25, making $52,500 to date. The mine is leased to the Imperator-Quilp company.

Republic, June 3.

CANADA

BRITISH COLUMBIA

The Standard Silver-Lead M. Co., operating the Standard mine, near Silverton, has sufficiently advanced No. 6 adit to enable the miners to drive a cross-cut to the ore-shoot on that level. This shoot of silver-lead ore has been well opened on No. 5 adit, those workings extending from No. 5 to No. 4. The orebody has been followed below No. 6 by a winze. The concentrating mill and aerial tramway are both under construction and probably will be in operation by August.

Decisions Relating to Mining

Specially reported for the MINING AND SCIENTIFIC PRESS.

ACTION TO RECOVER FOR DRILLING—CONTRACT FOR CORE DRILLING

In an action to recover for services in drilling under a contract calling for 'core' drilling, the fact that the first five holes were drilled by hand did not make the drilling by hand a separate and independent contract, where the hand drilling was also 'core' drilling.

A. J. Yawger Co. v. Buttz, (Indiana) 91 Northwestern, 568. April 1910.

TITLE TO OIL

The owner of land has no specific title to the oil therein until it has been removed from the earth. Petroleum oil is a mineral, and while in the earth it is part of the realty. If it moves from place to place by percolation or otherwise, it forms a part of that tract of land in which it remains for the time being, and if it moves to another tract it becomes a part and parcel of such tract, and it forms a part of some tract until it reaches a well and is raised to the surface, and then it first becomes subject to distinct ownership separate from the land and is personal property, the property of the person who has taken it from the well into which it came. This rule applies whether the oil moves, percolates, or exists in pools or deposits. In either event, it is the property of and belongs to the person who reaches it by means of a well, and severs it from the realty and converts it into personalty.

Bender v. Brooks, (Texas) 127 Southwestern, 168. April 1910.

TAXATION OF MINERALS.

Where the ownership of the surface and of minerals under the lands has been separated, an assessment and sale for taxes of mineral rights in a tract of land is a sufficient description of the ownership of the property in such minerals, and a tax deed containing such description is not void for uncertainty. The payment of taxes on a tract of land by the surface owner is not payment of taxes on minerals beneath the surface owned by another person and separately assessed with taxes in the name of the owner of minerals.

McGraw v. Lakin, (West Virginia) 68 Southeastern, 27. April 1910.

MINING RIGHTS

Mining rights must include incorporal hereditaments lying in grant but not in seisin; such as rights of way over the surface, the right to dig and drive slopes and entries, and the like rights of an intangible nature and incapable of being delivered of possession by the owner. Such rights include not only the minerals, but right of way and other uses of the surface necessary for the enjoyment of title to the minerals.

McGraw v. Lakin, (West Virginia) 68 Southeastern, 27. April 1910.

MINING LEASE—EFFECT OF NEW LEASE

Where the lessees under a mining lease accepted a new lease containing a part of the same and other property, and containing material provisions inconsistent with the old lease as to certain rights and liabilities under the original grant, such new lease constitutes a surrender of the old lease by operation of law as to so much of the land within the old lease as was included in the new. But the surrender of such old lease by the execution of the new, imposing different obligations not being a condition of the grant, could not effect the interests of a prior attaching creditor as to rights previously created and then existing against the tenant in the leasehold estate.

Hughes v. Farmers' National Bank, (Vermont) 76 Atlantic, 33. May 1910.

Personal

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

J. W. FINCH is at Goldfield.

S. F. SHAW is at Elkton, Virginia.

JAMES W. NEILL is in San Francisco.

O. H. PACKER is at Sutter Creek, California.

WILLIAM C. GREENE, of Arizona, is in San Francisco.

GEORGE E. COLLINS returned from Wisconsin, June 3.

H. FOSTER BAIN is in SaltLake and will go to Virginia City.

WALDEMAR LINDGREN was in San Francisco and has gone to Nevada.

C. H. VOLL has gone to Valdez, Alaska, where he has opened a branch office.

H. VINCENT WALLACE has returned to El Paso from Mora county, New Mexico.

M. A. NEWMAN, manager for Cia. Minera Jesus Maria y Anexas, is in San Francisco.

WALTER S. BICKLEY has been elected president of the Penn Steel Casting & Machine Company.

ELLARD W. CARSON, of Los Angeles, is manager for the Colonial Mining Co., near Quartzsite, Arizona.

ROBERT E. CRANSTON will be at Wonder, Nevada, for two weeks, examining the Nevada Wonder mine.

J. R. FINLAY has been selected by the Michigan Tax Commission as State Appraiser of mining property.

JAMES W. MALCOLMSON was in San Francisco last Saturday on his return from Alaska, and has gone to Mexico.

HERBERT C. ENOS, of Mexico City, has completed an examination of mining properties in Jalisco for New York interests.

JOHN M. BOUTWELL, consulting geologist for Phelps, Dodge & Co., is making a geological survey for the Moctezuma Copper Co. at Pilares de Nacozari, Sonora, Mexico.

WILLIAM J. HALL has been appointed assistant to the general manager of the Federal Mining & Smelting Co., and RUSH J. WHITE has been appointed superintendent of mines for the same company.

S. W. BRETHERTON, of San Francisco, has been engaged as consulting engineer for the Adaven Mining & Smelting Co., of Nevada. He is also consulting engineer for the Dominion Placer Mining Co. in Plumas county, and two copper properties in Shasta county, California.

The purchase which has just been consummated by the UNION IRON WORKS CO. of San Francisco of the good-will, patterns, records, etc., of the RISDON IRON WORKS, is of interest to those familiar with the history of manufacturing in the West. The United States Steel Corporation recently purchased the site and plant of the Risdon Iron Works, but did not take over any of the equipment, and through its acquisition by the Union Iron Works Co. the latter has added materially to its position as a large manufacturer of mining machinery, etc. R. H. Postlethwaite, formerly manager of the Risdon Iron Works, will superintend the department created by this consolidation. Back in the '60s the Risdon Iron Works operated a boiler shop at Bush and Market streets, San Francisco, and in 1849 the Union Iron Works Co. was started by James and Peter Donahue. Both of these companies have been large factors in the development of the Pacific Coast, being pioneers in the design and installation of the heavy mining machinery used in the old Comstock days and also equipping some of the largest mines in the Transvaal and Australia, and have had honorable careers. The Risdon Iron Works will be missed, but the Union Iron Works Co. having acquired its business and records and with the addition contemplated to its already large plant, will be able to continue the manufacture of mining and dredging machinery, boilers, etc., and to furnish spare parts for machinery already in service.

Copper Producers' Association Report

The monthly report of the Copper Producers' Association for May, issued June 8, gives stocks of metal on hand June 1 as 165,995,932 lb., compared with 165,559,908 lb. on May 1. Production for May was 126,962,544 lb., against 118,095,223 lb. in April. Domestic and foreign demand for May aggregated 126,522,520 lb., an increase of about 2,000,000 lb. over the previous month. The detailed statement follows:

Stocks of marketable copper of all kinds on hand at all points in the United States May 1, 165,558,908 lb.; production of marketable copper in the United States from all domestic and foreign sources during May, 126,962,544 pounds.

Deliveries of marketable copper during May: For domestic consumption, 84,543,963 lb.; for export, 61,978,557 lb. Total, 126,522,520 pounds.

Stocks of marketable copper of all kinds on hand at all points in the United States June 1, 165,995,932 pounds.

EDITORIAL

HIGH TEMPERATURES were the topic of the meeting of the Faraday Society in London on May 23, but the discussion was not a heated one.

THOUGH Congress is a national body, it shows signs of having come from Missouri. Sixteen congressional investigations are now under way.

FAULTS have puzzled many an engineer, and the discussion of the problems of faulting, by Mr. C. F. Tolman, Jr., in this issue throws much light on perplexing cases.

POVERTY-STRICKEN is a word apparently not in the lexicon of the Anaconda group of properties. Their current assets are given in a statement recently made public as over $45,000,000, or an excess over liabilities of more than $30,000,000.

JAPAN is a country of dense population, but the necessity of safeguarding youth is there none the less appreciated. A recent labor law provides that children under twelve years of age may not be employed in factories, and regulates the hours of labor of older workers.

POPULAR election of Senators assumes greater possibility since the Senate passed, on Tuesday last, the resolution amending the Constitution. This has already passed the House, and when approved by the Legislatures of three-fourths of the States, will become the law of the land.

REPORT has it that the United States Smelting, Refining & Mining Company has exercised its option on the Gold Road mine near Kingman, Arizona, making an outright purchase at $1,700,000. The mine has been an active producer and is said to have 300,000 tons of $10 ore in sight.

JAPANESE mines and mining have an added interest derived from the forthcoming visit of the American Institute of Mining Engineers to Japan, and Mr. Yamaguchi's description of the Nishisawa mine, near one of the objective points of the trip, is therefore timely as well as interesting.

CHIEF JUSTICE WHITE will head a committee, of which the other members are Justices Lurton and Vandevanter, to revise the rules of practice in courts of equity, formulated in 1852. If our legal practice can be changed from a trial of skill of opposing counsel in the avoiding of technical errors, to the prompt obtaining of substantial justice, much will be gained.

EXCELLENT work has been done by the Colorado Geological Survey, especially in the tungsten district of Boulder county, and at Montezuma. This work has been recognized by the Legislature, which has just increased the annual appropriation to $15,000. We are sorry to record at the same time that the State Geologist, Mr. R. D. George,

is now in a Denver hospital as a result of overwork, and trust that he may soon recover and resume his field work.

ERRORS in type-setting and proof-reading lead to many curious mistakes. Fortunately they are usually obvious. Occasionally they mislead. In the interesting description of the 'Gold Quartz Deposits of Porcupine, Ontario' by Mr. Reginald E. Hore, appearing in our issue of April 29, misplaced figures made him responsible for the statement that the saving by amalgamation at the Dome mine is 48 instead of 84 per cent. In the new mill now being built the combination of amalgamation and cyanidation will give an unusually high rather than a low extraction, as might have been inferred from the statement as it was printed.

TALK of a copper merger has again been rife, and the improved foreign demand for metal has steadied prices a bit. Consideration of the impending new production, however, induces pessimism as to natural improvement in prices, and the threatened criminal proceedings by the Government against officers of the Standard Oil and American Tobacco companies suggest caution in forming new monopolistic combinations. Any merger of copper producers that did not control production and raise prices would not offer sufficient inducement to attract the majority of producers. Court decrees may modify the Sherman law, but they seem ineffective as regards the law of supply and demand.

GRUBSTAKE funds have been responsible for the discovery of many important mines despite the well known dissipating influence of a jug and a convenient shade-tree. In Colorado an effort is being made to systematize prospecting by means of a general fund, raised through the efforts of the *Denver Republican,* and administered by a committee from the Chamber of Commerce consisting of Messrs. Max Boehmer, James Doyle, and E. Le Neve Foster. It is proposed to grubstake prospectors, to regularly inspect their work, and to test their finds. An excellent feature of the plan is the proposal to send recent graduates of the School of Mines with the prospectors. The scheme ought to eliminate much of the waste of ordinary prospecting, it will certainly advertise the State, and it may make good prospectors out of the young graduates. The last is by no means the least important feature, for more and better prospectors are needed rather than more engineers. It is by no means certain but that greater rewards will accrue to the school men who learn prospecting than to those who devote themselves to engineering.

FINANCING mining enterprises is a matter that demands, and fortunately is receiving, much carefnl study. Legitimate mining involves sufficient risk at best, and, while in any system of estimating probable returns there must be a large unknown element, that constitutes no reason against eliminating as many variables as possible. We discussed recently some of the conditions under which capital could be obtained in London for mining. In the current issue of *The Mining Magazine,* Mr. M. H. Burnham begins a series of articles on 'The Finance of a Mine,' in which he details the correct methods of appraising mines and stocks. This discussion is extremely valuable both from the point of view of those who would buy, and of those who would sell. There is probably as much ignorance among mine owners as to what sort of examination a property should be able to stand in order to make it readily salable, as there is among buyers of mining stocks who speculate on the chance of selling to some later but more optimistic 'investor.' Mr. Burnham points out the fallacy of adding together 'positive' and 'possible' ore, and announces the theorem that "the risk-rate for each block should vary inversely with the number of sample sections, and directly with the tonnage therein." This principle will be developed and its application explained in later articles.

The Hegemony of the Pacific

In his Charter Day address at the University of California, Mr. Theodore Roosevelt remarked: "It is on the Pacific that the great crises of the future have to be met and faced." This obvious truth is worthy of further exposition, and a brief review of the more salient features of the present status and probable future development of international interests on this great ocean is worth while.

The Pacific Ocean has an area equal to one-quarter of the surface of the whole globe, or one-half of its water surface, stretching from pole to pole, and its coast-line of 47,000 miles includes territory belonging to each of all the principal nations of the world. These nations may be divided into four great groups, the Anglo-Saxon group, including the United States, Australia, Canada, and Great Britain; the Oriental group, embracing Russia, Japan, and China; the Teutonic group, including Germany and the Netherlands; and the Latin group, comprised by the Mexican and South American republics. The interests of the Netherlands and Germany are centred in colonies belonging to those nations, while Great Britain appears in a dual rôle, as the mother country of Australia and Canada, and as the European power having the greatest commercial interest in the Orient. The Latin-American republics may be dismissed without any further mention, since their history for the century past indicates that they will not exert any marked influence in Pacific affairs in the immediate future. The following table gives interesting and significant data regarding the other countries:

	Area, sq. mi.	Population.	Annual revenue.	National debt.
United States	3,756,884	103,992,727	$894,876,855	$1,039,861,531
Russia	8,647,657	160,095,200	1,379,591,803	4,588,502,684
Japan	147,655	51,458,037	284,428,325	1,305,901,499
China	4,278,170	433,500,000	21,221,722	601,916,605
Australia	3,076,894	5,405,714	244,002,008	1,530,631,158
Canada	3,729,665	7,358,000	85,093,404	323,930,279

The consideration of this table must be prefaced by calling attention to the fact that both in the United States and China many of the functions of government are performed by State or provincial authorities, allowing a corresponding decrease in the national income. In a recent thoughtful article, Rear-Admiral A. T. Mahan has discussed the influence of the Panama Canal upon sea-power in the Pacific. Without minimizing the importance of naval and military strength it is scarcely possible to over-emphasize the strategic and cohesive power of commercial interests, the political value of invested capital. This was strikingly illustrated recently when a people noted for their diplomatic skill, the Chinese, executed the cleverest diplomatic coup of their history by borrowing $30,000,000 from a syndicate of English, German, French, and American bankers and pledging the revenues of the Manchurian provinces as security. The events which have been steadily shaping themselves since 1898 had, by the beginning of the present year, practically shaken off the grip of China's sovereignty from her three Eastern provinces, with no prospect of its ever being regained. By the negotiation of this loan, and the clever basis upon which it has been placed, China has reasonably secured the sovereignty of these rich and important provinces. Nicholas Murray Butler once strikingly referred to "the cohesive force of public plunder," and the adhesive power of invested capital should not be overlooked. This should not be taken in any derogatory sense: it is natural and normal. Each of us, for example, reads daily of the death of estimable people in various parts of

the world, with scarcely a flicker of emotion, but when we see chronicled in the daily journal the death of one who is attached to us by ties of former associations or kinship we are profoundly moved. The political vicissitudes of Chinese provinces are matters of little more than academic import until millions of foreign capital have firmly attached to them a significance which they previously lacked.

Recently there have been frequent references to 'dollar diplomacy' as though it were an American invention rather than the tardy recognition of the trend of European diplomacy for the last decade, in all cases where diplomacy can be dissociated from military strategy. The commercial position of the United States is much like that of a wealthy farmer who by the growth of his interests has gradually been led into banking and trade. That the methods of banking and trade are not those of agriculture is too obvious for remark, but that our international relationships are now markedly different from those of even so recently as two decades ago, apparently needs emphasis.

The hegemony of the Pacific must necessarily appertain to the nation that possesses the greatest interests in the Pacific. Great Britain has held the leadership; Hongkong is the second seaport of the British Empire, and the Dominion of Canada, the Commonwealth of Australia, New Zealand, and the British East Indies are strong outposts of Great Britain in the Pacific. But the future development of Canada and Australia must inevitably widen the gap that already exists between their interests and those of the mother country; British interests in the Pacific will gradually become Canadian and Australian interests, and these latter will not quickly become great enough to dominate the situation. Since the battle of Manila bay the trend of events has steadily been forcing upon the United States the hegemony of the Pacific. Whether we desire it or not, this responsibility can not be evaded. The future will show whether we, born of English blood, will in turn take up the white man's burden intelligently, unflinchingly, and with cheerful heart perform our task.

A Notable Reunion

It happens that this month four distinguished engineers long connected with the mining industry, and who have had much to do with the mining history of California, have been in San Francisco. We do not often publish eulogies of our friends who are still living, but they will in this case pardon, we hope, some reference to their work. Three of them have retired, but one is active. They are Messrs. A. J. Bowie, of Yokohama, Gardner F. Williams, of Washington, D. C., Waldemar Lindgren of the same city, and Louis Janin, of Los Olivos, California. Not only have these gentlemen rendered distinguished service to mining in California, but all of them have made the profession their debtor by contributions to technical literature. Mr. Augustus J. Bowie was for many years a resident of San Francisco, during which period he was active as a mining engineer in many places on this Coast. He was especially interested in gravel mining, and in ditch and dam construction. He, however, also had experience in quartz mining, and designed and built the first of the large mills in the Black Hills, South Dakota. He was consulting engineer for the famous North Bloomfield hydraulic mine during its palmy days, and was connected with other large gravel-mining and ditch enterprises in both this State and Idaho. Mr. Bowie is the author of 'A Practical Treatise on Hydraulic Mining,' which, though published in 1885, is still the standard work on that subject. It contains descriptions of the use and construction of ditches, flumes, wrought-iron pipes, and dams, with much of value on the flow of water on heavy grades, and its applicability under high pressure to mining, and the tables are especially valuable and are standard. Mr. Bowie went to the Klondike in 1897 for a syndicate, of which Mr. James R. Keene of New York was the head. He has been absent from this State for the past nine years, during part of which period he has been engaged in mining enterprises in the Philippines and for the Japanese Government. He is now making a visit home, but will shortly return to Japan.

Mr. Gardner F. Williams was also interested years ago in gravel mining in California, being connected with mines in Placer and Butte counties. In the latter he was with the old Cherokee hydraulic mines. A long time since he went to South Africa to report on some possible hydraulic ground, and while in London became connected with the De Beers Consolidated, which controls the great Kimberley diamond mine. He subsequently became manager at that property, a position he held until he resigned to be succeeded by his son, Mr. Alfred Williams, also a Californian. While manager of the De Beers, Mr. Williams sent to California for much machinery, and he also took men from this country to help him in his work. Mr. Williams is the author of a standard work on diamond mining, 'The Diamond Mines of South Africa,' which is beautifully printed and illustrated. Since his retirement from active mining work he has made his residence in Washington, D. C., but makes an annual journey to California to visit relatives and friends.

Mr. Waldemar Lindgren, now of Washington, D. C., is one of the most distinguished members of the U. S. Geological Survey, being chief of the division of Metals and Metallic Ores. He was for some years a resident of California, when offices were first maintained by the Survey in San Francisco, being then associated with Mr. H. W. Turner, Mr. G. F. Becker, and others. Later he resided near Auburn, in Placer county, while engaged in studies of the auriferous gravels. The field work of his forthcoming treatise on the 'Tertiary Auriferous Gravels' has been completed, but the volume has not yet been published. Mr. Lindgren is the author of many papers published by the U. S. Geological Survey, and is well known for his contributions to the knowledge of the genesis of ore deposits. He has succeeded to the position long held by Mr. S. F. Emmons on the Survey, and has much of the same peculiar hold on the esteem and affection of mining engineers here and abroad that Mr. Emmons had.

Mr. Louis Janin, who has retired to his ranch in Santa Barbara county, was one of the earliest of the group of mining engineers who came to the West from Freiburg to begin the practice of his profession. For many years he was actively engaged in its various branches. He left his mark particularly in his metallurgical successes in milling Comstock ores, and was long one of the most active and sought-after consulting engineers in America. He has written much on subjects connected with both mining and metallurgy, and still interests himself in them. His last active work was in determining important geological questions for the North Star Mines company of Grass Valley. For some years before that he had given up the examination and management of mining properties and confined his activities to work as a geological and mining expert witness in important litigation between large mining companies. One of his sons, Mr. Louis Janin, Jr., was a pioneer in cyanidation, and another, Mr. Charles Janin, follows his father in consulting work, and is one of the authors of the bulletin in 'Gold Dredging' recently issued by the State Mining Bureau. Throughout the lives of all these men runs a vein of achievement. They are successful. They have influenced their times and their profession broadly because they are broad men looking at things in a broad way.

Graphic Solution of Fault Problems

By C. F. Tolman, Jr.

A common occurrence in mining is to have a drift on the vein meet a polished wall, on the other side of which no ore is discovered. The life of the mine depends upon rediscovering the ore, but in many cases the vein is never found again. Occasionally the break is older than the ore deposit; the ore solutions may not have passed through the fault gouge, and so no ore exists beyond the break; but in every case where the break is younger than the ore, it exists somewhere beyond the 'trouble', as the Cornish miners call the fault. One superintendent may be unfortunate in his search; the next may have more knowledge or better luck, and when the vein is found he has scored a hit with the owners. Finally, if the ore is valuable and the superintendent unsuccessful, an expert in faulting may be called in to collect, study, and plot all data, but meanwhile important evidence may have been obliterated, which could have been observed when the fault was first found. For these reasons every man engaged in mining should be interested in fault problems.

The study of faults must be carried on according to the methods of applied geology, and the methods of detailed and exact geological mining investigation are of but recent development. For instance, in the somewhat generalized mapping of a large area, geologists once believed it only necessary to consider the vertical component of fault movement, an assumption which is entirely inadequate when accurate graphic investigations are undertaken. J. E. Spurr, in his excellent text-book 'Geology as Applied to Mining', emphasizes the occurrence of fault movement in all directions on the fault plane, but vertical sections, so universally used to portray generalized geological structure, show only the vertical component, and the importance of horizontal displacement, and pivotal fault motion, was not thoroughly appreciated, until the San Francisco earthquake gave emphasis to these factors.

It is strange that in the standard text-books on geology, faulting has received such incomplete and unsatisfactory treatment, and so little attention has been paid to accurate graphic methods of solution, especially when we remember that nearly thirty years ago R. W. Raymond published a summary of Hoefer's work on faulting,[1] involving the application of descriptive geometry to fault problems. Hoefer appreciated that faulting may involve movement in any direction on a fault plane, and that translatory movement may be combined with rotatory movement. With the exception of this article, no exposition of the graphic methods applicable to these problems has appeared in English until recently.[2] The engineer confronted by such problems must discover original solutions, remembering what he can of his early studies in 'Churches Descriptive Geometry', or be probably overlooks the possibility and value of the graphic solution, and may not know just what data it is necessary to collect in order to solve the problem.

The problems presented below are selected from those given in the laboratory courses in structural geology at the School of Mines of the University of Arizona since 1905, by myself and assistants, especially Theodore B. Chapin. The methods given are the most simple of the many that I have used both in engineering practice and teaching. The discussion is confined as closely as possible to the graphic solution of a set of type problems, and only the briefest possible statement of the various kinds of fault motion is made, with such a summary of fault nomenclature as is necessary for understanding them, and with a brief statement of the practical bearing of some of the solutions. The reader desiring a summary of the phenomena by which faulting is detected, as well as the modern ideas on the general subject of faulting, is referred to a paper entitled 'Methods of Investigating Problems in Faulting',[3] and to the valuable discussion in *Economic Geology*[4] for 1907, 'How Should Faults Be Named and Classified?'

Nomenclature of Fault Movement

A direct measurement of the amount and direction of fault movement on the fault plane is, unfortunately, not often possible; at times only the direction of movement, or the perpendicular distance on the fault plane between the two broken portions of the faulted body, is known; or again, possibly only the component of the fault movement in a vertical plane, or in a horizontal plane, or in a plane perpendicular to the trace of the faulted body on the fault plane. Since measurements in all these different planes are made, and, further, since the complete measurement in any one plane often cannot be taken, a complete and orderly set of names for all these is desirable, and is of great assistance in the discussion and solution of fault problems. Therefore the nomenclature previously suggested[5] is introduced here, with the substitution of the word 'normal' for the word 'vertical' throughout, on account of the criticism that the measurement there called 'vertical displacement' is not vertical, when the fault plane is inclined, but normal to a horizontal line. When rotation and translation are combined, these names are applicable to the movement at any given point of the break, the amount of the movement changing with the distance from the pole. In this case, however, a complete solution of the problem involves only the location of the pole about which the known angular rotation will produce the displacements observed; for it is evident that a combined rotation and translation can be considered as a pure rotation, and translation can be considered as a pure rotation about an equivalent pole. The term 'angular displacement' may be used, and the location of the pole designated.

Methods of Projection

In fault problems we have to deal with at least two planes, namely, the fault plane and the faulted vein, dike, or stratum. (Hereafter the word 'stratum' will be used for any faulted body which has two dimensions of decidedly greater magnitude than the third.) This involves representation in three dimensions, and only the four methods most valuable for our purposes will be mentioned, two of which are discussed and used.

1. *Mine Models.*—The use of mine models has become increasingly popular in the last twenty years; their development being due largely to the need of giving a clear idea of workings, veins, and faults, to non-technical judges and juries. More recently they have been found to be valuable in impressing still less technical stockholders. To those with experience underground, and a trained geometrical sense, models have little if any advantage over mine maps.

2. *Stereogrammatic Projection.*—An effective method of indicating spacial relations is by means of a diagram of a block; mine workings, fault planes, veins, etc., are located by measurements along the edges of the block. Of the various methods of projecting these blocks, the isometric is the most valuable, and is the only one used in this discussion, and is described below.

3. *Orthographic Projection on Two Mutually Perpendicular Planes.*—This is a simple and at the same time a valuable method for representing underground conditions. However, the projecting of the two perpendicular planes on the single plane represented by the sheet of paper is

[1] Raymond, R. W. 'Hoefer's Methods of Determining Faults in Mineral Veins'. *Trans.* Amer. Inst. Min. Eng., Vol. 10, pp. 456-465.

[2] Reid, H. F. 'Geolometry of Faults'. Bull. Geol. Soc. of America, Vol. 20, pp. 171-196. This valuable contribution goes over some of the ground covered in this discussion. The author does not adopt the simple concept presented by me in a following article regarding rotary fault movement. Mr. Reid conceives that poles of rotation may lie at various angles to the fault plane, and introduces artificial solutions, involving such movements as a rotation about, and translation along, one and the same pole.

[3] Tolman, C. F. *Mining Magazine*, New York, February 1906.

[4] *Economic Geology*, Vol. 1, No. 8; Vol. 2, No. 1, 2, 3, 4, 5, 6, and 7.

[5] Tolman, C. F. 'How Should Faults Be Named and Classified?' *Economic Geology*, Vol. 2, pp. 506-511.

unsatisfactory where the workings are extensive, and especially where they are not confined to a definite plane, and for most purposes, especially for the solution of problems, the following method is superior.

4. *The Two-Level or Contour Method.*—Mines are mapped by 'levels'. Exploration and extraction workings are generally driven at regular intervals (100 ft. is the most common interval) and the group of workings at each depth is a 'level'. Given the trace of a vein on two levels and it is completely located unless it suffers some distortion lower down, in which case the new position is shown by the traces on the lower levels. By using the simple method of mapping faults and faulted strata on two levels

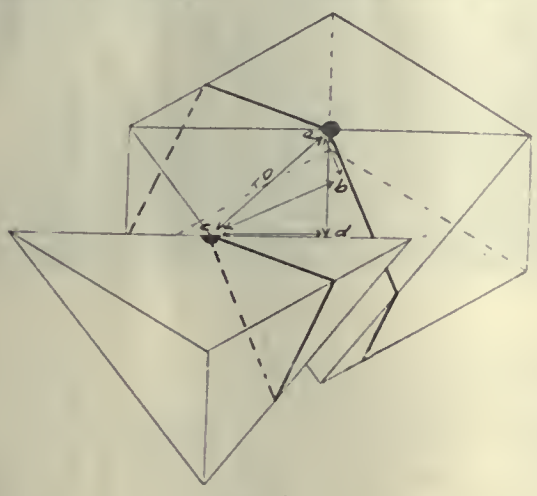

FIG. 1.

(one 100 ft. below the main or reference level), the graphic solution of fault problems is made easy, and is the one adopted in the following discussion.

Measurements of fault movement are made in the following planes:

1. On the fault plane. All such measurements are designated as 'displacements'.

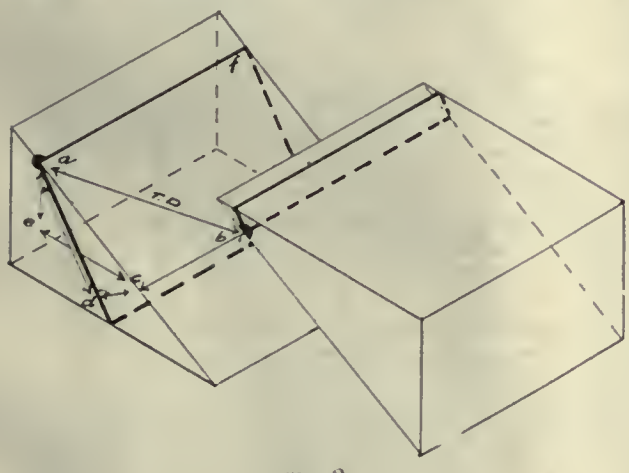

FIG. 2.

2. On a plane normal to the trace of the faulted body on the fault plane. These measurements are the 'separations'.

3. On any perpendicular plane. 'The throws'.

4. On a horizontal plane. (Generally the earth's surface.) 'The heaves'.

These are represented in Fig. 1 to 4 and in each diagram the vein or stratum is represented to contain a lens or nodule which has been split open by the fault movement, thus indicating at a glance the direction and amount of fault displacement.

The displacements. Fig. 1. The 'total displacement' is *ac*. This is taken as the hypothenuse of a triangle, the adjacent side of which is parallel and the opposite side perpendicular to the trace of the faulted stratum on the fault plane; *ab* is called the 'parallel displacement', and *cb* the 'perpendicular displacement', and the angle $cab = e$. With *ac* again as the hypothenuse, a second triangle is constructed with the opposite side a horizontal line, and the parallel side normal thereto; *ad* is called the 'normal displacement' and *cd* the 'horizontal displacement'.

The separations. Fig. 2. These, as defined above, are in a plane normal to the line *af*, and as this line happens to be horizontal, the measurements in this particular case are in a vertical plane, and are therefore both separations and throws. The 'total separation' *ac* lies in the fault plane and has already been named 'perpendicular displacement'; *ad* is the 'parallel separation' and *cd* is the 'perpendicular separation', the latter being the only important measure-

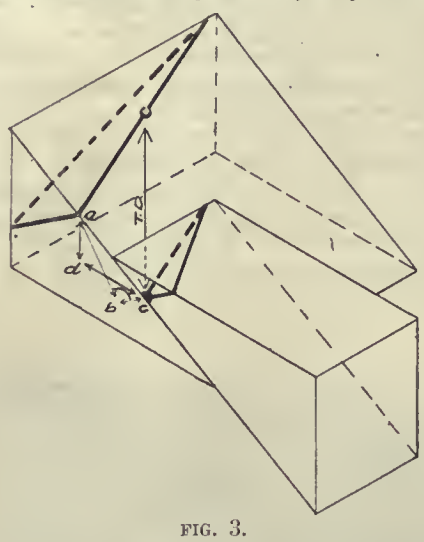

FIG. 3.

ment of this set. It is, of course, the shortest distance between the two faulted portions of the stratum or the faulted portions produced; *cc* and *ae* are, respectively, the 'horizontal' and 'normal separations'.

The throws. Fig. 3. These are measurements in any vertical section, and are of importance because in making structural sections the throw in that section must be determined. With reference to any particular fault plane under consideration, the section normal to the strike of the fault is the most important, and if the direction of the section is not designated in describing a throw, this section is understood. In the figure *ac* is 'total throw', *bc* is 'parallel

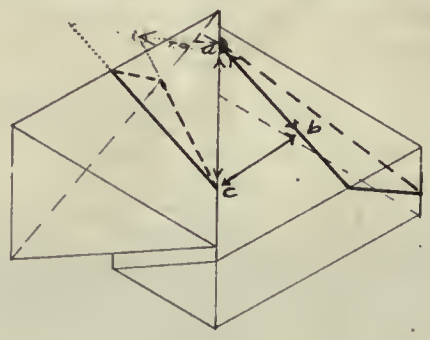

FIG. 4.

throw', and *ab* is 'perpendicular throw', *cd* is 'horizontal throw', and *ad* 'normal throw'.

The heaves. Fig. 4. The heaves are measurements in a horizontal plane. In the figure *ac* is 'total heave', *ab* is 'parallel heave', and *bc* is 'perpendicular heave'.

Isometric Projection

Space is represented in Fig. 5 by a cubical or rectangular block, position in which is determined (1) by locating the point in a horizontal plane, and (2) locating this plane according to its distance below the top of the block. The edges of the block are projected orthographically on the plane of the paper, by directing the line of sight at a corner of the cube. The edge of the block representing depth is projected vertically, and the other two edges are projected upward to the right and left, the angle between the projections being 120 degrees.

The projections of the edges of the block are shorter than the projecting edges, and all measurements parallel to these edges are measured in the 'isometric scale'. Those lines parallel to the diagonal *bc* are the only ones projected full length. Of all directions in the horizontal plane, the 'short diagonal' *ad* is most inclined toward the line of sight and is therefore most reduced in projection. Points are usually located by taking the coördinate measurements parallel to the edges, but occasionally it is convenient to take measurements parallel to either of the two diagonals, and it is therefore valuable to know the ratio of these three scales. To determine this ratio, revolve the block around the diameter *bc* until the top coincides with the plane of the paper, taking the position *a'bd'c*. The ratio of the lengths of the projections of a given distance, taken (1) parallel to 'long diameter' *bc*, (2) the edges *bd*, and (3) the 'short diameter' *ad* is $bd' : bd : b'd$.

To find the length of the projection of the line kl in these three directions. Take bl' equal to *kl*. Draw $l'l''$ perpendicular to *bc*. bl'' is the length of the projection parallel to the edges. Take dl''' equal to this isometric length (bl'') and as $l'''\ l'''\ ''$ is parallel to *bc*, $dl'''\ ''$ is the length of the projection when *kl* is parallel to *ad*.

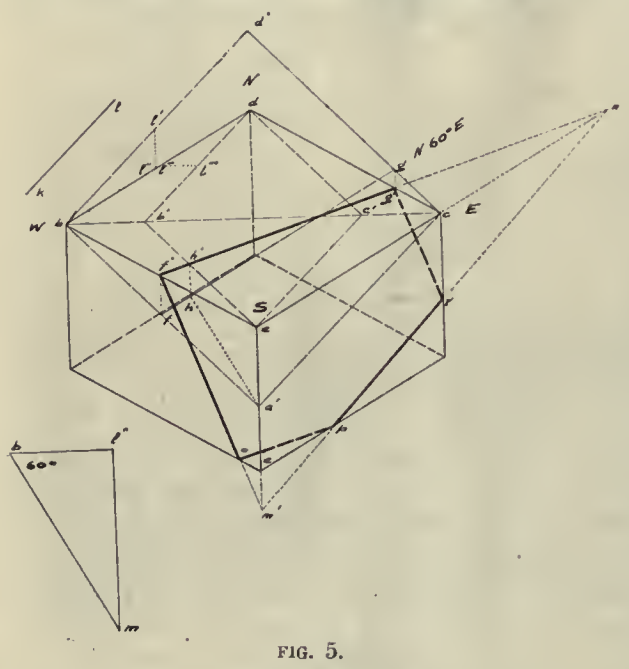

FIG. 5.

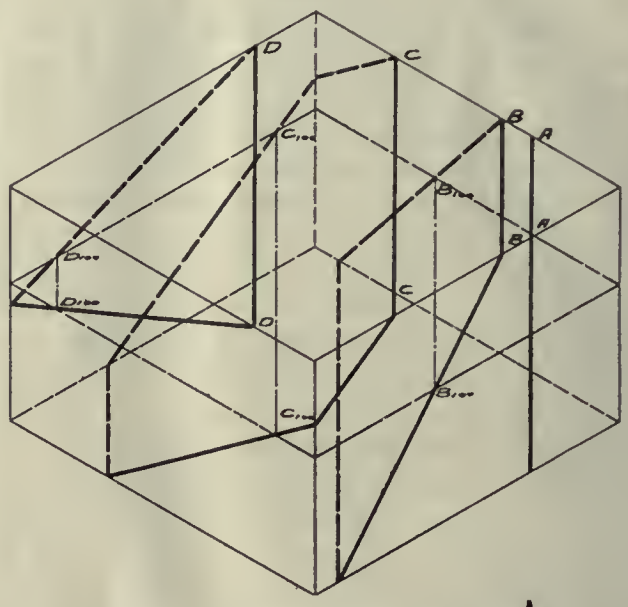
To draw a plane whose dip and strike are known. Locate the points of the compass on the block. (In Fig. 5, north is parallel to the 'short diagonal'.) Lay off *fg* in the revolved position (*a'bd'c*) of the top of the block according to its strike (north 60° east). Draw *a'h* perpendicular to *fg*. Locate *f'g'* in its proper position in the isometric block by drawing *ff'* and *gg'* perpendicular to *bc*. *a'h* then becomes *ah'*; *a'h* is equal to *bl'*, therefore *bl''* is the corresponding isometric length. The dip of the stratum *f'g'* is given as 60° to the southeast, and since *ah'* is taken perpendicular to *f'g'*, a plane passed through *ah'* and *ae* will show the dip. Constructing a triangle with a 60° angle, and the isometric equivalent of *ah'* being used as the adjacent side, the opposite side *ml''* shows the proper isometric length to be laid off on the edge of the cube. Point *m'* is taken this distance below *a*. By connecting *m'* and *f'* trace *f'o* is obtained. By projecting the edge *ac* and the line *f'g'* until they meet in point *n* and connecting *m'* and *n*, trace *pr* is found, and the other traces are then drawn in.

The two-level or contour method of projection. The relation of the isometric to the graphic method of projection is shown by Fig. 6 and 7. In these, every plane, unless perpendicular, is located by two lines. The heavy line (*BB*) is the map of the plane on the reference level, and may be called 'the strike line'. A line of light dashes the trace of the plane on the level below and this is the contour line of the plane. Any number of contours may be used if the plane changes dip or strike with depth. The dip of the stratum is shown by the distance between the strike line and the contour, and the 'dip triangle' may be constructed by drawing a line perpendicular to the two traces

FIG. 6.



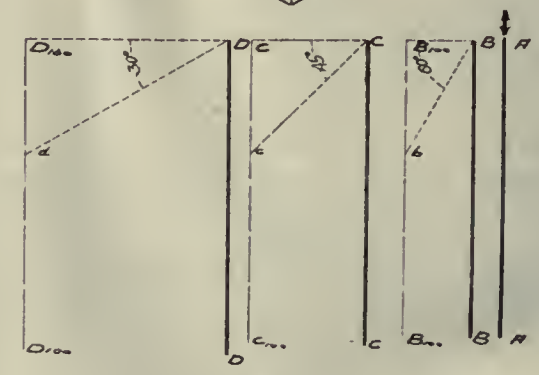


FIG. 7.

($B\,B_{100}$) and laying off to scale 100 ft. on the contour ($B_{100}b$) and completing the triangle ($B_{100}\,B\,b$).

The scheme of lines chosen to represent planes, traces, lines, points, etc., used in this and succeeding discussion, is shown by the legend below.

Visible trace of plane with side of block.
Invisible trace of plane with side of block.
Intersection of plane within block.

Trace of plane with reference surface (strike line).
Trace of plane with surface 100 ft. below.
Projection of intersection of any planes.
Projection rotated back into reference surface.
Projection of a line—portion above reference surface is light solid line; that below is dot and dash. Dip of line theta is given by rotating same around its projection. (See Fig. 5).
A point is located by a small circle and the distance above or below reference plane by a dotted line.
Construction lines.

(To be Continued)

IT IS ESTIMATED that in the process of mining and treatment of the zinc ores of Missouri, one-half of the metal is lost. In much of the copper mining, in some of the gold and silver mining, and other metal mining, the waste is estimated to be from one-fourth to one-half of the total product. In the mining of coal, the average loss throughout the country is nearly one-half of the total product. this loss amounts to nearly 250,000,000 tons of coal each year. And in this the waste does not cease with the mining of the coal; it continues even on a larger scale in the burning of the coal brought to the surface, as it is consumed in the furnaces for the development of power and light.

Early-Day Mining in California

The maps and scenes depicted on this page will serve to call to mind again the early days of mining in California, and will revive many memories among those who participated in the stirring events which occurred when the placer mines of the State were pouring forth their golden millions.

THE MINERS.

It was labor, not capital, which was omnipotent then, and rich ground was abundant for those who sought their fortunes with pick, pan, and shovel. In the 'days of '49', and for years after, thousands who came to California hunted for and worked claims in the southern mines, including the counties of Amador, Calaveras, Eldorado, Mariposa, and what are now Fresno and Madera counties. C. D. Gibbes, a civil engineer who was among the early arrivals

MAP OF CENTRAL CALIFORNIA, 1852.

in the goldfields, made, among others, the map shown herewith. This was printed in 1852 and was at that time considered a very perfect one indeed.

The sketch of 'The Miners' is one the counterpart of which may still be seen in many places, but was universally characteristic when placer mining was the principal industry of the State, and men sunk shafts to bedrock to get at the shallow auriferous gravel along the gulches and on the flats near the streams. The old bowlder and gravel piles still seen in hundreds of places in the mining regions are about the only historic marks remaining of the past industry of thousands of miners long since passed away.

The two views of Placerville, Eldorado county, and Mariposa City, Mariposa county, may be taken as pictured types of the mining camps of the early 'fifties'. The structures were of temporary character, usually built on the sides of a central street. Few of those who came to California in those days expected to remain after they had dug their fortunes from the soil, and fewer still had even a remote idea of the possibilities of the permanent future of the State or its varied industries. They came to mine and then to leave for 'The States', again with no thought of continued residence. Most of the old-time towns are still in existence, though numbers of once flourishing camps have been long since abandoned with the exhaustion of the neighboring placer fields. Those which still exist are of a decidedly different appearance and character from what they were when the nomadic miner was the only inhabitant. For the loan of the lithographs from which these cuts have been made we are indebted to Stephen Vivian, whose father was in California in the days of '49.

In the earlier history of gold mining in California most of the precious metal was procured from surface washings in gulches, canyons, river bars and beds, and for many years an enormous amount of gold was derived from these sources. In 1852 the placer miners of the State mined out $81,294,700 in gold. Gradually, however, the area available for this kind of mining was narrowed, as ground was worked out, and then attention was turned to other sources of supply. Limited areas of these surface placers still exist in portions of the State.

When the quartz veins and hydraulic and drift mines

PLACERVILLE, ELDORADO COUNTY.

were found, companies built ditches to bring in the water to the gravel claims, and mills to crush the ore from the quartz veins. It became necessary to employ capital as well as labor in the mining operations of the State. The miners gradually stopped mining for themselves so universally, and became permanent residents of the little mining camps and larger mining towns where they were sure of steady em-

MARIPOSA CITY, MARIPOSA COUNTY.

ployment in the mines and mills. With them disappeared the romantic features of mining so graphically depicted by Bret Harte and writers of lesser note. There are, of course, still many prospectors in the mountain and foothill countries, as well as many miners who work their own claims, but the majority of the mining population is now engaged in work for the various companies which are operating the mines on a larger scale than is possible for an individual.

The Nishisawa Gold Mine

By Yoshikatsu Yamaguchi

According to a tradition, this mine was worked as a lead mine in the era of Kokwa (1844 to 1847). At that time the mine was governed by the priests of temple of Nikko, and working gold and silver ores was prohibited under the Tokugawa government. In spite of this, the mine was worked for silver and gold by Denyemon Konoike, a wealthy Osaka merchant. The mine was therefore confiscated, and Nagai, high commissioner of Nikko, was punished.

The mine lay idle until 1893, when the villagers of the district were granted permission to work it, and it was soon taken over by Gentaro Takahashi, who undertook exploratory work and in 1893 found a rich zone of auriferons and argentiferous bismuth ore on the Asahi level. During the following seven years, barrel amalgamation was carried on until 1902, when a disastrous flood carried away all the surface plant. Interested local gentry then organized the present company. Since that time exploration has been carried on, and the expansion of the surface plant has been steady. The mine is situated within a very rugged area in the mountains of the Nikko group (see map), and may be easily reached by way of Lake Chuzen-ji where there is an old temple called the Futa-ara Ginsha on the north beach. The mine is about 17 miles from Nikko. Near the mine there is a precipitous pass called Sanno, consisting of an ascent of about 2½ miles from the mine to the plain of Senjo-ga-hara; the road through this pass is now under reconstruction and is almost finished, so that travelers will be enabled to go by cars shortly after. From the above-named plain, the road is even and good along the beach of Lake Chuzen-ji to Chugushi. Between Chuzen-ji and Umagaeshi, there is a steep descent to Nikko. The road is very good from the hamlet down to the town; electric cars run four miles from Nikko to Futamiya, where the main road from Nikko to the Ashio copper mine branches toward Hosoo. As said before, the mine is situated among high mountains belonging to the Nikko group. Narrow valleys and steep ravines have been cut by erosion, so that there are frequent waterfalls. Although the mountain sides are covered with thick forests, rock-cliffs appear in many places in the mining area, the rock which contains the gossan and forms the outcrops of quartz veins being left unattacked by weathering, on account of its relative hardness and soundness as compared with the surrounding rocks. Those outcrops frequently occur coinciding in positions with lines of valleys, forming cataracts.

The rock at this mine is chiefly quartz-porphyry, frequently covered by liparite. The porphyry is white or light gray, and contains remarkable quartz crystals. The rock often appears to have been changed into tuff, shading imperceptibly into the unaltered rock, while those parts coming in contact with Paleozoic rocks contain abundant inclusions of quartz, clayslate, and sandstone, so that the liparite resembles a breccia. The liparite is of gray or brown color; it is loose, platy, or columnar, or frequently with a rhyolitic structure. It occurs in the higher parts of the mountains, being rarely found in the valleys. It is occasionally interbedded with clastic rocks; but it is not accompanied by any volcanic ash. A small area of sandstone and clayslate is also exposed, the strikes of both being obscure. The clayslate has been partly changed into hornfels by the metamorphic action of the quartz-porphyry.

The ore deposits are fissure veins, occurring in the liparite and the liparite tuff; but they are not found in the Paleozoic nor in the quartz-porphyry. The outcrops, though occurring in over two hundred places, do not permit a determination of the real number of veins, because they differ in strike and dip as well as appearance, though belonging to the same vein. The veins are perhaps fifty or sixty in number and may be divided into two groups: (a) those striking N. 60-90° E.; (b) those striking N. 40-50° W. The first group includes the greater number of the veins, having steeper dips, mostly 70 to 90°. The veins pinch and swell, being only 2½ in. wide in some places. Out of a little more than 200 veins, 144 have a width of over 6 inches.

The gangue consists of white and colorless quartz, containing native gold, argentite, wolframite, proustite, maldonite, galena, zincblende, chalcopyrite, pyrite, etc. The distribution of these minerals varies in parts of the veins. They often occur in symmetric bands, the richest part being usually next the central zone consisting of argentite and wolframite. The veins are frequently crossed by fault fissures, so that the levels exposing the veins exhibit very varied and complicated features. The richest shoot now worked is considered to have been formed by the joining of several veins. Maltidite rich in gold and silver was found and mined many years ago; but it is not found at present, although it occurs in some places underground in a little quantity. Exploration has not made great progress, only a few veins having been partly developed. The nature

MAP OF NIKKO DISTRICT, JAPAN.

of the deposit, it is believed, gives promise of great future prosperity.

The veins are explored by levels 5 ft. wide and 6 ft. high. Cross-cuts are driven from the level to search for other veins. When a rich zone or an ore-shoot is found, a winze is then raised or sunk. The minerals are thus worked by both overhand and underhand stoping. There are four important levels: the Yamanokami, the Asahi, the Daikoku, and the Kainn. The Kainn level, the highest, is a cross-cut started in a valley called Nebarisawa, and it is now being extended. The Daikoku level is the highest of the other three, while the Yamanokami level is the lowest one, that is, nearest to the water-line of the main valley. The Yamanokami adit will be made the main haulage road in future, because it is nearest to the metallurgical works, now being enlarged. The Asahi and Yamanokami levels are connected by winzes, and have many important working places. The No. 3 vein is at present worked chiefly on the Asahi level. The Daikoku level is now closed off.

At present rock is broken by hand drilling and dynamite. The output of the mine for the ten months from January 1907 was 4363 tons. The average content of the ore is 0.001 to 0.002% of gold and 0.0478 to 0.800% silver. There is natural ventilation and drainage. Transportation underground is carried on by half-ton cars running on 9-lb. rails. The ore is brought to the picking-house and dumped over a horizontal grizzly with 2-in. spaces. The oversize is classified into rich ore, common ore, and waste. The rich ore is cobbed, while the common ore is crushed by a

Blake crusher. The crushed ore, together with the grizzly undersize, is allowed to fall upon grizzlies with 1-in. spaces and is sorted, according to value, into best ore, common ore, middle ore, poor ore, and waste. The best ore and the common ore are sold to the Hitachi and the Ikuno mines; and the poor ore and the ore finer than ½ in. are again divided into ore to be sold and ore to be treated in the metallurgical works.

The mill consists of one horizontal grizzly 4 ft. wide and 36 ft. long with 2-in. spaces; and six inclined grizzlies 5 ft. wide and 8 ft. long, three of which have 1-in. spaces, and the remaining three have ½-in. spaces; and one 4 by 10-in. Blake crusher. In this plant, 1320 tons of ore is treated monthly, the average value of the finished ore being 0.05 to 0.0125% gold and 0.0582 to 0.0900% silver. The poor ore obtained by picking is crushed by the breaker to below 1-in. size and passed through a grizzly with 1-in. spaces. The grizzly oversize, together with the ore between 1 in. and ½ in., is crushed by a roll-jaw crusher, and is allowed to pass over a ½-in. screen. The undersize is then sent to a Huntington mill, together with the fine ore, which comes directly from the picking work.

In the mill the crushed ore passes through screens, of 30 meshes per one *sun* or about 1.2 in., to amalgamated copper plates, where the gold and silver amalgam are caught. The pulp passing over the plates is sorted by a hydraulic classifier into sulphide ore, sand, and slime, each being dressed on Overstrom and Wilfley tables. The products from the concentrators are wolfram concentrate, sulphide concentrate, sand, and slime. The wolfram and the sulphide are both sold, while the sand and slime are to be subjected to cyaniding. The plant used for fine crushing and amalgamation is one 4 by 10-in. Blake crusher; one inclined grizzly, 5 ft. wide and 8 ft. long with ½-in. spaces; three 4 by 12-in. roll-jaw breakers; four rotary ore-feeders; four 3½-ft. Huntington mills; four amalgamated plates, 3 ft. wide and 7 ft. long; three Overstrom concentrators; and four Wilfley concentrators.

The auriferous and argentiferous sand from the dressing works is leached in vats by cyanide solution, the solution being 0.2 to 0.4% cyanide in strength. The solution which has passed out from the zinc-boxes is raised up to solution tanks by centrifugal pumps, and conducted into distribution tanks, where the solution is restored to the proper strength, ready for the leaching of fresh ore. The gold precipitate is melted in crucibles with borax and sodium carbonate for gold and silver bullions.

The slime is poured with cyanide solution of 0.2 to 0.4% strength into the leaching-vats and agitated by man-power with agitators attached to the vats. The pulp is conducted into discharging-vats, whence it is forced into a filter-press by means of a force-pump. The gold and silver solution passing from the press, free of slime, is then sent into zinc-boxes for precipitation. The barren solution from the boxes is sent into the distributing-tanks. The precipitate is fused and refined for gold and silver bullion in the same way as described in case of the sand-treatment.

The cyanide plant consists of one 5 by 10-ft. strong-solution vat; two 5 by 10-ft. weak-solution vats; four 5½ by 15-ft. sand-vats; two 5 by 6-ft. slime-vats; three 4 by 5-ft. gold-solution vats; four 2 by 2 by 12-ft. zinc-boxes; two 4 by 7-ft. discharge-solution tanks; one 3-hp. centrifugal pump with 3-in. delivery pipe; one filter-press with plates 2½ ft. square; one 1-hp. pump for the filter-press. With this plant 600 tons of ore will be treated monthly, producing 201 oz. gold, 310 oz. silver, 3 tons of wolframite concentrate, and 72 tons of sulphide concentrate.

Power is obtained from a boiler and a Pelton water-wheel, taking its water from the main stream at the mine. Power is also transmitted about seven miles to the mine from the electric-power station at Shyobu-ga-hara. The boiler is a multi-tubular type of 40 hp. and drives a 40-hp. engine. The electric-power plant consists of a turbine driven by a flow of 1020 cu. ft. per minute under a head of 85 ft., generating 123 effective horse-power. It is geared to a 75-kw. three-phase dynamo.

The ores to be sold are put into bags (kamasu) and sent on horseback to Nikko, whence they are transported by railway to the Ikuno and the Hitachi mines. The transportation for the 19½ miles to Nikko costs 13* yen per ton. The cost of transportation from Nikko to the Hitachi mine is 2.22 yen per ton, the distance being 104 miles. Part of the waste is used for packing the stopes underground; and the rest is piled on dumps. The mine water runs out by gravity. The waste water from the dressing and metallurgical works is made to precipitate its slime in settling-ponds, built on the ground just below the metallurgical works. The cyanide tailing is deposited behind rubble walls near the cyanide plant.

Re-Surveying Land

By P. B. McDonald

Re-surveying land on which many of the corners have been lost is as delicate a surveying problem as can ordinarily be undertaken, and requires judgment and experience. F. Hodgman, in his excellent handbook on the subject, remarks that, "Many very intelligent gentlemen suppose that if the surveyor can but find one of the corners of the original United States survey he can readily determine the position of all the rest from it." He then cites the following instance which is well worth repeating. "I have measured sections 22 and 23 on a level prairie, along the line of highways, where no obstacles of any kind interfered to prevent accurate work. I took the greatest possible care in the chaining to have it as accurate as chain work can be done. On the north line of section 22 my chaining tallied exactly with that of the United States survey, viz., 79.60 [chains]. On the north line of section 23 my measurement was 80.96, that of the United States survey, 80.40—a difference of 56 links (some 37 feet). Fortunately, all the corners of the original survey on this two miles of line were well preserved, and the distance between quarter-post and section corners was uniform on the same section in both sections. But suppose that a part of them had been lost, and it was required to restore the middle section corner (N.E. of 22) from the remaining ones. Omit all consideration of corners north and south, and there remain four different solutions of the problem, depending on which corners were lost and which preserved. Of these different solutions, one would place the corners 9⅓ links, one 14 links, one 18⅔ links, and one 28 links, all east of the true corner. This is not by any means an extreme instance, as I have observed discrepancies twice as great." Such a case might not affect farm or timber lands to any serious extent, but not infrequently in mining districts a rich body of ore crosses a disputed line, so that every foot in a mile strip is worthy of serious consideration. It often happens that one surveyor will fail to find the marks of an original corner, while another, more apt in discovering the evidence, will hit upon it readily.

The ordinary mining engineer is called upon to do re-surveying of land so seldom that he is apt to be at a loss how to proceed. He remembers that there is a vast amount of discussion of the subject in his old textbook used in college, but the quantity of this usually appalls him, so that he merely looks up the general rule and goes out in the field, trusting to find convenient landmarks that will solve the problem. The following remarks upon such work are by no means conclusive; they merely represent some methods which have been found to be convenient in the upper peninsula of Michigan.

Preparatory to re-surveying land, write to the State Capitol for the original survey notes, which will be furnished at a small charge for copying. If subdivision work is still in progress, as in many of the Western States, this record can be obtained from the U. S. Surveyor General of that State. In the Middle West, where the government surveying was completed years ago, apply to the State Land Commissioner. These original survey notes are indispensable where any doubt exists as to the correct boundaries; they

*1 yen = 49.8 cents.

describe the stakes left, the bearing-trees, line-trees, and general topographic features of the country traversed. The following is a sample of the notes for one mile:

5.22	chains.	Sugar maple 9 in. [in diameter], line-tree.
12.20	"	Fir 10 in., line-tree.
40.02	"	Set sugar-maple post, quarter-section corner.
Bearing-trees.		Yellow birch 12 in., N. 62 E., 26 links. White pine 20 in., S. 70 W., 27 links.
75.00	chains.	Stream, course S.E.
80.04	"	Set alder post, section corner.

Bearing-trees described as follows, etc.

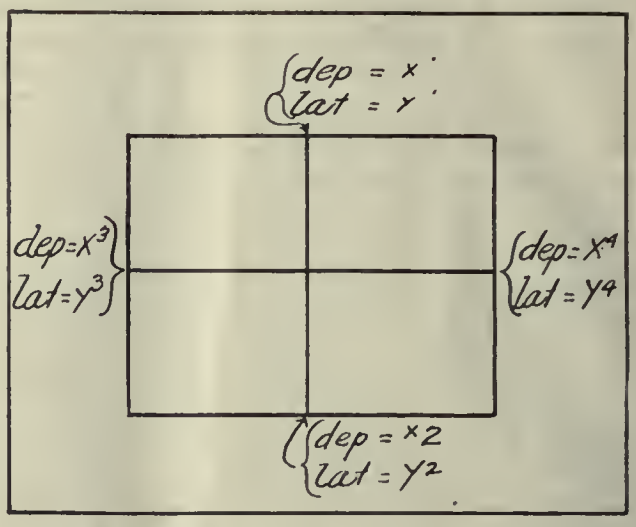
Often not a trace of the original corner can be found, until, from the notes, two stumps are located corresponding in direction and distance with the bearing-trees. Then usually careful digging with a shovel at the measured spot will disclose the rotted remnant of a stake under the vegetation and sub-soil. Although foreign to the habit of most surveyors, "there is great virtue in a pick and shovel intelligently applied to the finding of corner posts and monuments." Also the best, and sometimes the sole, evidence of a corner has often been destroyed by an ignorant person striking deep into the ground, expecting to find a sound stake, and casting away the decayed wood or filling up the hole of a rotten stake without observing it. The same precaution applies to chopping away the encroaching bark which tends to hide a blaze on a bearing-tree; frequently all that remains of a lettered blaze is a narrow slit which, if carefully cut back, will disclose the scribe marks of the original surveyors. In general, it is better to chop from the outside in, than to try to enlarge the slit by slicing, for the latter method usually cuts off the faint lettering.

In some cases where no stakes or bearing-trees could be found, the original line-trees (which were merely blazed without lettering) have been discovered and taken as authority, since the purpose of re-surveys is to establish as nearly as possible the stakes placed by the original surveyors. For convenience in referring to the original survey notes, they can be copied in the field notebook and the pages of the book numbered; then on a sketch map of the sections being surveyed, in the front of the book, each section line can be marked with the number of the page where the notes for that line are copied.

Some customs of the original government surveyors are here given. Two bearing-trees were left for each section corner and quarter-stake, usually in opposite quadrants; present practice is to leave four. Bearing-trees at a quarter-stake were cut by a steel 'scribe' with the inscription '¼.' At section corners the trees were marked with the number of the section, the township, and range. Bearing-trees, in addition to being blazed and marked, were notched just above the ground, so that where there remains only a short stump, the notch identifies the tree. Section corners were squared at the top and notched on four edges; the notches indicate how many sections there are in each direction in that township, in this manner identifying the stake. Thus the northeast corner of section 14 would be notched twice on the north side, four times on the south, once on the east, and five times on the west. Only the section corners and quarter-stakes were put in; the sixteenth or 'forty' posts and the centre of the section were left unmarked.

The general rule to follow in establishing lost corners is as follows: "Retrace the known lines of the description and find how the lengths and directions of these lines by your survey agree with those of the same lines as laid down in the original description. Then run the unknown lines and place the lost corners so that they will bear the some relation to the known lines and corners as they are required to do by the description of the original survey."

The centre of a section is the point of intersection of the two lines connecting the north and south, and the east and west quarter-stakes. Knowing the total latitudes and departures of the quarter-stake, the latitude and departure of the centre-pin can be conveniently computed by analytic geometry, thus, by an hour's work in the office, saving considerable time in the field.



$$\frac{y - y_1}{x - x_1} = \frac{y_2 - y_1}{x_2 - x_1} \qquad (1)$$

$$\frac{y - y_3}{x - x_3} = \frac{y_4 - y_3}{x_4 - x_3} \qquad (2)$$

Substitute total latitudes and departures in equations (1) and (2), paying attention to the sign in each case. Equation (1) will be the equation of the line connecting the north and south quarter-stakes; equation (2) will be the equation of the line connecting the east and west quarter-stakes. Solve the two equations together simultaneously, and the values obtained for x and y will be respectively the departure and latitude of the centre of the section, since that is the only point common to both lines. After determining the coordinates of the centre of the section, its angle and distance from a quarter-pin can be easily computed.

As to subdividing quarter sections into forties, instructions from the General Land Office have not been uniform. Several commissioners have maintained that the dividing lines should be straight lines running through the sections to points on the section line, but other commissioners and general practice have decreed that the quarter-quarter posts are to be placed at points equidistant, and on straight lines between the section and quarter-section corners, and between the quarter-corners and the common section of the section. The latter method is the simpler and easier of the two, and the one generally used.

Previous to starting the work, it will pay the surveyor to take a walk around the sections in question, and talk with old residents thereabouts. Very often through the use of a little time and tact, he will learn whether or not stakes and fences are authentic, besides acquiring a working knowledge of the country that will enable him to plan his work to advantage.

It is desirable to do the taping with a tape divided into links and chains so that all readings are direct. A tape two chains long can be purchased for about $4, and if the chainman has learned the knack of twisting a tape through the figure-eight into a circle he can carry it conveniently around his neck. Many surveyors prefer a light transit such as is used for mountain work in the West; a No. 4 instrument on a No. 5 tripod is a popular combination.

Oil is the greatest foe of catching gold on amalgamated plates. The catching of the gold is done by the gold breaking the mercury surface and sinking beneath it; the gold sinks in the mercury just as ore does in water. But since the gold is in small fragments of no great weight and the surface tension of the mercury is strong, the surface of the gold must be clean or else the mercury will not wet it, and the gold will float on the mercury just as a greasy needle may be made to float on water. Grease may be removed by the use of an alkali which converts it into soap. It is much better to prevent grease getting on the ore or in the battery than it is to try to remove it afterward.

The Repeal of the Apex Law

By W. P. Rodgers

Mining men generally feel that there is something wrong with the apex law, as is shown by the many references to it in our mining journals. The following is an attempt to show that the legislators of the apex law had in mind fissure veins only; that the law is not adaptable to other and anomalous forms of deposits and should not be applied to them.

The whole mining industry may be divided into coal, iron, quartz, and placer mining. The last of these, having no relation to the apex law, will receive no further attention. Lands containing the coal and iron mines in the East were taken up under the common law and have no bearing on the apex law. It is worth noting, however, that peace and prosperity has attended these branches of the industry, operating under the common law, in contrast to the litigation among followers of the apex law. There is no geologic reason why a coal miner should not have the same right to go down on his vein as the quartz miner has on his. There is no geologic reason why the same general law should not regulate both these branches of mining. Typical vein mining is carried on in Michigan, in the great copper mines, under the common law, but no complaints are made of the industry being hampered because of this. If the apex law is a fundamental conception, it should be found regulating the greatest branches of the industry instead of the least. If it had the merits claimed for it, better conditions would exist where it does operate than where it does not; yet the opposite is true.

On certain Indian reservations in the Northwest, where mining privileges are granted to prospectors, the clause containing the extralateral-right feature is stricken out. The Philippine Commission adopted a mining code that excludes the apex law in its entirety. In certain mining camps in the United States owners have voluntarily abrogated the apex law, by adopting the common law, where the geologic conditions were such as to endanger the rights of adjoining owners. This has created industry where the operation of the apex law hampered it, and has stimulated where the old law has discouraged. In speaking of the Arizona copper camps, James Douglas says: "The wonderful development of mining in this district has unquestionably been brought about through this liberal policy." Again: "From every point of view, therefore, I believe the companies of both districts have benefited, and undoubtedly the population of both has prospered, and the whole of southern Arizona has advanced with rapid strides through this abolition of the law of the apex and the voluntary adoption of the common-law rule."* All these facts show that there are serious limitations to the apex law. The action of private ownership in withdrawing its support, and of the Government in omitting it in late legislation, shows a change in opinion regarding it and that general experience with the apex law has proved unsatisfactory. Surely this evidence of its being unsound is opposed to the idea that it is a 'fundamental conception'.

The adoption of either law where applicable would have a tendency to involve rather than simplify. This demands a definition of such terms as lead, lode, vein, deposit, and orebody. Definitions of these terms have never been rendered, either by geologists or courts, to convey a general yet specific and concise meaning, without ambignity. It is impossible to do so, because of pertinent conditions. Geologists have classified orebodies, and where the difference between classes is distinct, little difficulty would arise in applying the better law. These would be the exception rather than the rule. The geologic conditions of a mine, to a certain point, may be suited to one law, but upon further development, they may change sufficiently to cause confusion in knowing which law to apply, or so distinctly as to be covered by the other law. Where the difference between classes is indistinct, who is to judge which law to apply? If any person is capable of knowing, it is the geologist, yet his judgment would hardly prevent a plaintiff from resorting to an action at law, nor would any precedent be strong enough to satisfy him.

The right of the miner to go down on his vein appears, on its face, to be true enough to be a maxim. Writers have declared it and courts have decided cases on it, basing their opinions on the right of discovery, and as a reward for his labors and incentive to further discovery. In the first place, has not the discoverer as much right to the length of his vein as he has to its depth and width, based on right of discovery? Who has a greater right to it? It appears that his right applied to length is a variable one. At one time it was only 50 ft., at another 400 ft., at another 1400 ft., and even 3000 ft. in an association claim. At the present time it is 1500 ft., as a Federal limitation. If justice, based on right of discovery, demands that a miner follow his vein on its width to its depth, it also demands that he follow it to its length. Why is he restricted in his right as to its length? Furthermore, the discoverer is allowed a right only to what is included within his stakes. Beyond these he has no right whatever. He discovers a vein, and it may so happen that he locates that part which is unprofitable to work. Another prospector locates the extension, which proves to be the bonanza of the whole vein. Now what becomes of the 'right of the discoverer as a reward for his labors and incentive to further discovery'? The following from a speech by W. M. Stewart, Senator from Nevada, has been cited in support of the apex law: "To extend the preëmption system applicable to agricultural lands to mines is absolutely absurd and impossible. Nature does not deposit the precious metals in rectangular form descending between vertical lines into the earth." Did Mr. Stewart mean to say that soil was deposited in rectangular form? There is a law of deposition that governs soil and precious metals alike. That law is, where conditions are favorable deposition will take place, and, it may be added, without regard to geometrical form. When President Jefferson approved of the rectangular system of public-land surveys, he did not do so thinking that soil was deposited in 'rectangular form', but as an improvement over the then existing system of metes and bounds. It may have appeared that the 'dictates of plain justice' demanded that a man had a right to choose the productive soil, and enclose it by an irregular line of metes and bounds, as was the custom, rather than be compelled to buy it in rectangular form, the barren along with the fertile. The Senator's speech, instead of being sarcasm, furnishes us a good example of how a long-established custom of the division of real estate was completely changed to a system that had really less justice for the individual but more for the whole people, and which substantially put an end to litigation over boundaries.

It is said that a greater confusion of rights will result in a change from the apex law to vertical boundaries. That is to say, greater confusion will arise where there is a definite boundary to rights, than where that boundary is indefinite. It is not clear how any confusion can arise when the new claim is to be staked subject to all the rights claimed by the senior locator under the old law. The new law would take effect where the rights under the old law cease. This will make the transition gradual and without a nonconformity. No more 'confusion of rights and resulting inevitable litigation' can occur than if the new claim were staked under the old law.

It is affirmed that the apex law was made for the fissure-vein type only, and it seems that this opinion is held generally among both the friends and opponents of the law. Contemporaneous history supports this view, and the internal evidence in the law leads to the same conclusion. The Federal law of May 10, 1872, uses the words 'vein', 'lode', and 'ledge'. 'Deposit' appears but twice in all Federal legislation and Land Office regulations in connection with quartz mining. An examination of the State codes discloses the fact that those legislators have followed closely

*The Engineering and Mining Journal, Nov. 23, 1907.

the meaning in the Federal law by making use of the same terms. Another reason for believing that they had in mind 'veins' of the fissure type only, is, they did not mention any other. If they contemplated other orebodies, why did they not mention them? The language in which it is expressed is not such that something else or something more can be deduced by way of implication; it is specific. If they contemplated deposits with irregular boundaries, having a large superficial outcrop, the length and breadth of which are approximately equal, why did they adopt a long, narrow claim to cover it? The width of the claim appears to have been a variable, too, varying from 50 to 600 ft., the Federal limitation, but never equaling the length.

There is an example before us. The following is a quotation from the opinion of the Court of Appeals, in the case of Lawson *v.* The United States Mining Co.: "Where two or more mining claims longitudinally bisect or divide the apex of a vein, the senior claim takes the entire width of the vein on its dip, if it is in other respects so located as to give a right to pursue the vein downward outside the side lines. This is so because it has been the custom among miners, since before the enactment of the mining laws, to regard and treat the vein as a unit and indivisible in point of width, as respects the right to pursue it extralaterally beneath the surface; because the width of the vein is so irregular, and its strike and dip depart so far from right lines, that it is altogether impracticable, if not impossible, to continue the longitudinal bisection of the apex through the vein on its dip or downward course; and it conforms to the principle pervading the mining laws, that priority of discovery and location gives the better right, as is illustrated in the provision giving to the senior claim all ore contained in the space of intersection where two or more veins intersect or cross each other, and in the further provision giving to the senior claim the entire vein at and below the point of union, where two or more veins with distinct apices and embraced in separate claims united in their course downward. Rev. Stat., Sec. 2336."

The first thing engaging the attention is, that the "senior claim takes the entire width of the vein on its dip." That is to say, it is necessary to stake only one claim in width over any broad showing, whether that claim covers all the apex or not, as that senior claim will hold all the ground between the boundaries of the orebody. In an old established camp where mines have been working, on newly discovered ore-shoots, or by the invention of processes making lower-grade ore profitable, the senior claim may be enabled to extend its ownership over every parallel property and dispossess all other owners; a fact certainly not the intention of the framers of the law. It is true that the early miners were not accustomed to divide the apex. It is also true that the law of 1872 both expressly and impliedly does not intend that the side lines should be destroyed. The law is specific in stating that a claim shall not exceed 600 ft. in width. The deputy mineral surveyor is the only person authorized to move the boundaries of a claim. When the original location stakes are beyond the legal dimensions, he is authorized to move them in to the proper limits, but never to move them out when it is staked less than the legal limits.

There is an implied limit that the width should not exceed 1500 ft. If the framers of that law thought that 1500 ft. in length along the lode was enough for a claim, should not that be enough for the width, when the apex is that wide? But the interpretation of the courts is that the length of a claim is only 600 ft. when staked across the lode. Would it not seem as plausible to extend ownership along the vein to the full 1500 ft., the Federal limit, and dispossess the junior locator, as it is to extend the width, destroying the Federal limits and dispossessing every parallel junior locator? But it was done according to the custom of miners. What was the miners' answer at Leadville, Colorado? When the owners of claims there having the apex of those deposits came up for trial for their extralateral rights, there was not a jury that would grant them.

Again, the court says that it is impossible to continue the bisection of the apex throughout the vein. Has not the principle of that very thing been accomplished by private ownership in the way of amalgamation of companies? While it would in a sense be impracticable for each company to have continued operation on the same vein, they could have effected a working agreement, whereby each was to receive a certain percentage of the profits based on a proportional cross-section of the vein at the surface. Another argument for the apex law is based on "priority of discovery and of location gives the better right." Better right to what? To the vein, of course. If a discoverer has a right to the vein, he has as much right to its length as to its width and depth, which the laws do not grant him. If he has a right to it, he has a right to the best part of it, which is plainly not true in all cases. Curtailing his right a little more, he should have it at least to the full Federal limit, 1500 ft. along the vein, but not so in all cases. If the prospector happens to stake across his vein, he gets only the width of his claim, whatever that is, but it must not be more than 600 feet.

If he misses the vein altogether and stakes off at one side, he gets the better right to nothing at all, as a "reward for his labor and incentive to further discovery." If the prospector is fortunate enough to locate on the vein and along it, he will enjoy all the rights and possession accorded to the Federal limit, but how often is the vein exposed enough to do this? In the case of a broad apex his rights become more apparent. The trouble is in knowing where they cease. When the claim is located with the strike of the deposit, rights extend to the boundaries of the ore, wherever they may be. This is not a criticism of our courts. I am fully conscious that our system of jurisprudence is as good as any. The courts have done all that human judgment can do. History discloses the fact that their task has been arduous, but they have performed it with untiring zeal, sincere devotion, and a conscientious struggle for the right. The fault is not theirs; it is in the statutes. No court ever will be able to lay down a hard and fixed rule defining a boundary of rights while the statutes do not indicate any, only on condition. The law has not a general adaptability, it was not constructed for broad apices, it has been stretched beyond the intention of the framers, and is, therefore, no law at all.

The evil is fundamental and demands fundamental treatment. No remedial legislation, no revision, no modification along the old lines will do. A new principle must be established. Therefore, a repeal of the apex law is recommended. The laws of location, too, should go, as they fail to render the expediency they should. They are cumbersome to the prospector and shoulder on him unnecessary expense. In their place is recommended the 1500-ft. square claim, bounded by vertical side lines, as fixed and rigid as the North Star, without a proviso, without a condition in the law regulating it, which should be devoid of language implying instability. These fixed boundaries and determined rights will give a title that is unquestioned, and on this account will remove the causes that otherwise intimidate capital. The enactment of the common law will unify the whole mining industry, by bringing together the coal miner and the quartz miner. There is no valid reason why the common law should not be adopted: it has been done before. British Columbia made the change from the apex law and adopted the square location, and their laws have excited the admiration of every mining man who has had experience there. The Philippine code is expressed in parallel language. That system, already adopted within the jurisdiction of the United States, is an initial step.

Who is to construct the law? The lawyer says that the geologist should not, because he has not read Blackstone. The geologist thinks the lawyer should not, because he has not studied geology. A knowledge of both law and geology is necessary, and both are equally important. It would appear, therefore, that the law should be constructed by a special committee composed of lawyers and geologists. Let it be done with deliberation, with comprehension, with judgment and reason, and a law will be evolved that will deliver the development of all future discoveries from the burden that now encumbers it.

Combination Melting and Cupelling Furnace

By Will H. Coghill

Coke-fired melting-furnaces of sufficient size to hold large crucibles have been used for several centuries. In operating this type of furnace the melter is obliged to expose himself to intense heat while drawing the crucible from the furnace and pouring its contents. As the result of the recent development of the cyanide process in which the 'clean-up' must be given a preliminary treatment and melted, the furnace has been greatly improved, and we now have the tilting furnace in common use. This furnace is fired either by gas or gasoline; it rests on trunnions, and can be tilted through more than 90° by means of a crank, thus discharging the contents of the crucible, and relieving

TILTING MELTING FURNACE.

the melter from exposure to the heat. The burner is fastened rigidly to the pipe-line and must be shut off before the furnace is tilted. I am using a No. 40 Donaldson tilting furnace manufactured by the Denver Fire Clay Co., and have modified the burner connection at an expense of about $3, thus greatly increasing the usefulness of the furnace. The picture shows the furnace tilted ready for cupelling, with the burner made fast to the furnace by means of strap-iron, and connected to the gasoline pipe-line by a flexible copper hose furnished by the Pennsylvania Flexible Metallic Tubing Co. The copper tube is nearly as flexible as the ordinary steel hoisting cable of the same size, and is guaranteed to be non-corrosive and to stand 100 lb. pressure. With the burner connected in this way the furnace can be tipped to any angle below the horizontal without interrupting the blast. I have cupelled in this furnace, forming liquid litharge, which was drawn off through a pipe connected to an air-line by means of a hose. For this work a cement cupel was built in an old crucible. A board was made to fit snugly into the crucible, dividing it, in the direction of the axis, into two equal parts and to the under side was fastened the pattern which was to shape the cupel bowl. The cement was then tamped into place and the board slipped out and the pattern removed. The pattern was 7 in. long, 6 in. wide, and 1¾ in. deep with sloping sides and gave a bowl which after making allowance for litharge gutter had a capacity of 25 lb. of lead.

This furnace can also be used to demonstrate the roast-reaction process of lead smelting. The hearth bottom is built in the crucible, as previously described, except that the pattern is left out, thus giving a hearth with a plane surface in which a lead gutter can be cut. The pipe for applying the air-blast should be straight, and direct the blast against the side and end of the crucible, thus allowing the air to reverberate and become preheated before it comes into contact with the material to be roasted.

The accompanying table, showing a temperature test on this furnace, may be of some value to those considering the use of this type. The gasoline used was 62°B. (really petroleum naphtha) and was consumed at the rate of one gallon per hour. The temperature determinations were made with a Bristol thermo-electric pyrometer, with the fire-end placed about one inch from the bottom of the crucible. At 11 o'clock, after a preliminary warming and drying for one hour, the blast was turned on full force. At this time the outside of the furnace was barely warm. The blast was turned off at 11:35, and the continued rise in temperature indicated at 11:37 was probably due to a lag in the pyrometer.

Hinged Guide Shoes

The ordinary method of removing a cage from the shaft requires hoisting it above the surface level, taking out two of the guides held in place by bolts, dropping the cage to the correct position, swinging it out, and detaching the cable. To substitute another cage the reverse process is

HINGED GUIDE SHOE, KENNEDY MINE.

then necessary, the whole maneuver being awkward and time consuming. As a result, cages suitable for a special sort of work are not as often used as is otherwise desirable. At the Kennedy mine, Jackson, California, the superintendent, Webb Smith, has met this difficulty by using a hinged guide shoe, illustrated in the figure above. With this it is unnecessary either to have removable guides or to first hoist and then lower the cage. Instead, the latter is brought a little above the level of the shaft collar, the flat-headed locking pin shown is withdrawn, the cage swung out, and rope detached. At this mine the cages not in use are swung to one side on an overhead trolley, and are readily available at any time. The guide shoes when in place are locked by the pin shown. The head is shaped so that the pin when in position prevents any possible unlocking by accident.

Dredging in California

STAFF CORRESPONDENCE

The Yuba Consolidated Gold Fields, for which W. P. Hammon is managing director, is operating twelve dredges at Hammonton, situated on the Yuba river, twelve miles east of Marysville, California. The ground in which these dredges are being operated has an average depth of 64 ft. below water-line, being the deepest ground in California on which work is now in progress. In fact, the problems in connection with deep dredging were worked out here with the first two dredges that were built. Each of these was equipped with a digging chain of 6-cu. ft. buckets, and was designed to excavate 60 ft. below the water-line. The top soil, consisting of tailing deposited as the result of hydraulic operations years ago, has a depth of 10 to 30 ft.; the material between this and the bedrock is made up of compact bench gravel and modern river-wash. The value of this ground is 18 to 20c. per cubic yard. The other ten dredges, built since the first two were tried out, are equipped with 7-cu. ft. buckets. These twelve dredges handle an average of 100,000 cu. yd. per month of gravel per dredge, or about 3300 cu. yd. per day. Yuba dredge No. 13, under construction, an illustration of which is given herewith, is expected to be in operation next month. This was designed and built by the Yuba Construction Co., and has a 124-ft. steel digging ladder, carrying ninety 15-cu. ft.

YUBA DREDGE NO. 13.

buckets, by which excavating can be extended to a depth of 65 ft. below the water-line. The ladder, buckets, rollers, and lower tumbler have a combined weight of 676,150 lb. This dredge probably will have a capacity of over 10,000 cu. yd. per 24 hours. The operations at Hammonton are under the general management of Newton Cleaveland.

The Natomas Consolidated of California, one of the Hammon interests, is operating Natoma dredge No. 8 on American river, near Folsom, handling material at the rate of 500 cu. yd. per hour; this consists of heavy clay and cemented gravel, and is considered difficult ground. The same company's dredge No. 9, now practically ready for work, will be operated on Rebel hill, one mile from dredge No. 8. Both dredges are equipped with 15-cu. ft. buckets, the length of the ladders being such that digging may be extended to a depth of 55 ft. The placing of an order by this company for the construction of Natoma dredge No. 10 has been already announced. It is to have a steel hull, 150 by 50 ft., 10 ft. deep; is to have 15-cu. ft. buckets, and will be operated on Humbug hill, near Folsom.

The Oroville Dredging, Ltd., is operating five dredges in the Oroville district. Two of these are of the Yuba Construction Co. type, having 7½-cu. ft. buckets; two others are of the Bucyrus pattern, with 5-cu. ft. buckets; the fifth is a Risdon dredge, having 3-cu. ft. buckets, close-connected. These are working in ground running 12 to 15 cents in gold per cubic yard.

The Calaveras Engineering Co. is using a Lidgerwood-Crawford scraper-bucket excavator, a gravel washer, and gold-saving plant of the Risdon type, in working over the auriferous gravel of an ancient river channel close to the Calaveras river, three miles north of San Andreas. The material, lying on a schist bedrock in which are stringers of quartz, is dry, except between certain limestone crevices. The excavator consists of a car, resting upon rollers by which it is moved on a plank track. It has a 60-ft. boom upon which the scraper-bucket works, weighing 1½ tons, and having the capacity of 1½ cu. yd. The bucket is raised and lowered by means of a hoisting cable working over a sheave at the end of the boom; it is loaded by means of a drag-line running between a set of traveling sheaves in front of the floor plate. The loading and dumping is accomplished by means of an equalizing cable attached to the drag-line and front of bucket, and which passes over a sheave fastened to the bucket bail. The excavator has a bottom plate of steel, 14 ft. square, a 14 by 28-ft. floor plate of steel; between the two plates is a turn-table of 12 cast wheels resting on 80-lb. rails. The machine is turned by a single-drum winding engine, having two cables attached, whereby a complete circle can be made and the bucket operated on all sides. The machine is operated by steam-power, wood being used as fuel. Thus equipped, the machine has excavated to a depth of 35 ft. at this mine, and can be worked to a depth of 50 ft. without any changes. It handles 300 to 500 buckets of gravel in 10 hours. The material is dumped by the bucket into a 12 by 12-ft. hopper which constitutes the top part of washer and gold saver. It passes from the hopper through two chutes into an iron cylinder, 4½ by 22 ft., which revolves at 12 to 15 r.p.m., the receiving end being about 3 ft. higher than the discharge end. The upper part of the cylinder has ⅜-in. perforations, those in the lower 18 in. being ¾ in. The oversize discharges from the cylinder upon the stacker, by which it is carried to the dump; the undersize passes into an iron box that is lined with Hungarian riffles, in which 80% of the saving is made. The sand and gravel are then carried to a riffled sluice-box in which quicksilver is deposited, and finally it passes on to a 20-ft. sluiceway in which cocoa matting is used for recovering the fine gold. The cylinder and stacker are operated by a 15-hp. electric motor, and the water used in the cylindrical screen and sluice-boxes is pumped to the top of the washer from a ditch in the vicinity, from 150 to 250 in. being required. The channel being dredged contains a considerable amount of barren clay, occurring in layers. This is removed separately, and not allowed to become mixed with the gold-bearing gravel, as it would rob the sluices of gold. By utilizing the equalizer cable on the bucket the operator is able to excavate in layers, and thus remove the clay. A certain amount of water is pumped into the hopper by which the material is washed through the cylinder, the feed into the latter being so regulated as to make it uniform. S. R. Fox, manager for the company, states that the ground being worked averages 25c. per cubic yard and that he washed an average of 245 buckets of gravel per day of 10 hours during April, under unfavorable conditions. It requires two men on the excavator, one to operate, the other attending to firing, water-supply, and oiling; one man is required on the washer. All bedrock material, except the limestone, can be excavated by the bucket. By using a few sticks of giant powder on the limestone banks these may be broken down. The water supply required at the excavator is obtained at the washer. The washing plant is moved by the excavator equipment, by using a block and cables fastened to trees or anchors. This ground is being worked on the basis of a royalty.

Quicksilver in Mexico

The quicksilver mines in Mexico are few, past production has been irregular, and the amount now produced is exceedingly small. The most important mines are in Huitzuco, State of Guerrero. The deposits, very irregular, occur in Cretaceous limestone, filling cavities or as replacements. The ores are cinnabar in small amount, and a sulpho-antimonide of mercury in various stages of alteration, accompanying stibnite. As by-products of alteration, some sulphur and gypsum occur. Secondary alluvial deposits filling chimney-like cavities have been more import-

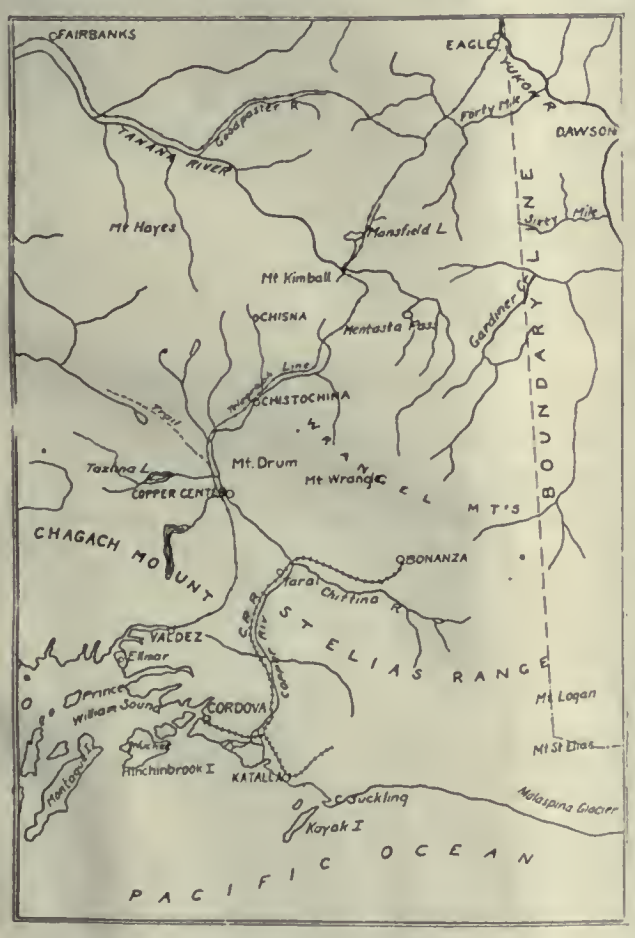
ant, though of low grade; many of these deposits are now almost exhausted. The other district is Guadalcazar, in the State of San Luis Potosi, with a small-scale production from irregular deposits in limestone. Working has now almost ceased. In both districts exploration is difficult, in view of the uncertainty of conditions. A thorough examination of the quicksilver properties might result in more intelligent development. The Huitzuco mines are now under option to an English syndicate.

In many Mexican mines cinnabar is occasionally found near the surface, especially in the States of Guerrero and Michoacan, associated with silver or copper ores. Many of these mines were discovered and worked during the Spanish domination, when the Government explored the whole country for quicksilver to supply the needs of the patio process.

Quartz Mining Near Valdez

By Anthony McCauley

It was not until the discovery of the rich veins surrounding Valdez that quartz mining became practical in Alaska. Here conditions are good, the climate is mild on account of the Japanese current, and transportation is easy, as the smelters can be reached by all-water transportation, the cheapest in the world. This marks the beginning of an era of quartz mining in Alaska, which from all indications will eclipse the records of even its famous placers. The little group of rich mines opened up around Valdez will be the



MAP OF SOUTHERN ALASKA.

incentive for further prospecting and work, and from this beginning it will spread, new discoveries will be made, and new towns spring up. From the time that the first discoveries were made and the first rich deposits opened up in the Cliff mine in the summer of 1910, prospectors ranged the hills and within a very short time a number of sensational finds were made, and specimens were brought in lavishly sprinkled with coarse gold. The snows beginning to fall early put a stop to prospecting for the winter, and development was to a great extent retarded by the lack of roads, and the difficulty of getting in supplies for the winter, but from all indications the present summer will witness the opening up of some of the most sensational mines ever found in any camp, as the veins are strong and the surface rock is phenomenally rich. The district is remarkable for the great extent of its mineral territory, covering an area of about twenty miles long by ten miles wide, the great number of veins, and the numerous properties from which 'specimen rock' can be obtained.

Synthetic Rubies

Staff Correspondence

The manufacture of artificial precious stones has always had a fascination to the physicist, and also, it must be said, to the swindler. The much-advertised but secret discoveries are to be treated with due caution. 'Imitation' stones, as distinct from 'artificial', have been with us since the days of the Romans, who produced beautiful glass imitations of almost every known stone, but the problem of producing a ruby or sapphire from pure corundum is of course quite a different matter. They have been formed in microscopic crystals, as also have diamonds, by simulating the condition under which it is supposed that the natural stones are formed, but they have never had any commercial value as yet. During the last few months London has been flooded with advertisements issued by a Paris firm called Tecla, that has recently established a business in England. The statements made in these advertisements have been taken with large grains of salt, for the claim that the rubies were real corundum, undistinguishable from the Burma or Oriental ruby, sounded too much like a trap to catch the unwary. Nevertheless, the claim appears to be a valid one, and the scientific explanation that has been issued seems reasonable and sound. Noel Heaton read a paper recently before the Society of Arts giving an account of the process.

The system of manufacture consists of building up a stone from tiny natural stones, fragments, and cutter's dust, and also from amorphous corundum, by means of the heat of the oxyhydrogen blowpipe. As long ago as 1819 a book on the blowpipe by E. D. Clarke described how if two pieces of ruby were placed upon charcoal and exposed to the blowpipe flame they would melt into one bead. About 1870 Gaudin revived these experiments, and in 1885 these stones were sold for a short time as 'reconstructed' or 'Geneva' rubies. The amount of skilled labor required in making them was so great that their cost was almost as high as that of the natural stone; and it was not until 1904, when Verneuil invented an automatic machine for conducting the operation, that the process became of commercial value. The principle on which it works is to first break the stones or cutter's refuse to powder, and then place a thin layer upon a small platinum disk. When this has been melted, a further supply of powder is allowed to drop gradually into it. Twenty-five years ago this addition of other grains was done by hand, a fact which accounted for the costliness of the operation. In Verneuil's apparatus the powder is contained on a sieve in the oxygen chamber, and an electrically-operated hammer gives the sieve a series of gentle taps, allowing the powder to drop through the sieve at a predetermined rate. This powder is carried along by the mixed gases to the fusion chamber and is made to impinge, in the midst of the flame, upon the platinum disk. The disk is gradually lowered and the melted material upon it, being withdrawn from the zone of fusion, begins to harden. The powder subsequently introduced by the blowpipe is fused upon the hardened mass, and thus slowly and by degrees a large stone is built up. This is called a 'boule', and it is usually pear-shaped. It takes about half-an-hour to produce one weighing from 20 to 30 carats. The old experimenters were doubtful of the value of the stones thus produced, for they expected that their structure would be amorphous, and that they would lack the optical and physical properties of the natural crystal. Mr. Heaton, however, states that these properties are faithfully repro-

duced and that the 'boule' is a single crystalline individual. The only way an expert can differentiate the artificial from the natural is by a study of such gas-bubbles as may be enclosed. In the natural stone these cavities are always found along the planes of crystallization with their axes parallel to the lines of cleavage. Sometimes there are so many of these parallel with each other, in two directions in each plane, as to give the structure technically known as 'silk'. In the artificial stone the cavities filled with occluded gas from the blowpipe retain their spherical shape and are distributed irregularly through the mass.

A great advance in the application of this process took place when Verneuil discovered how to use amorphous corundum instead of the small pieces of natural stone. A pure ammonium alum is prepared and introduced as fine powder just as was the natural powder. The flame decomposes it, by expelling the ammonia and the sulphuric acid, leaving a pure alumina. The stones thus formed are called 'synthetic', as distinguished from 'reconstructed'. In this process the coloring matter has to be considered. If none is introduced the resulting stone is a white sapphire. In order to produce the ruby color, a small proportion of chrome alum is added to the ammonium alum. For a long time the sapphire-blue could not be produced; cobalt was at first used as the base, but it was difficult to form its aluminate. This could be done by adding magnesia, but the presence of the latter resulted in making a spinel, or magnesium aluminate, instead of corundum. Finally it was discovered, quite unexpectedly, that titanium oxide gave the required tint. It will thus be seen that the two most valuable stones are being produced. They are sold at one-tenth of the price demanded for high-class natural stones, and the Tecla firm says that dealers will not buy, and pawnbrokers refuse advances on, any sort of colored stone. Truly an unfortunate circumstance for those who have hoarded that most beautiful, rare, and valuable stone, the pigeon-blood ruby.

The Venterskroon Goldfield

Much that is misleading continues to be published concerning the Venterskroon goldfield, the southern outcrop of the Witswatersrand system, where every geological formation on the Rand is repeated, except the payable reefs themselves. During the last twenty years there has been considerable prospecting by trenching, boring, shaft sinking, and every method of prospecting likely to meet with success, but so far a payable continuous line of reef has not been discovered. Patches of good ore there are in abundance, but they either thin out and disappear in depth, or become faulted and broken off to such an extent that their recovery becomes so expensive as to render mining at a profit impossible. It is this exact repetition of the Witwatersrand goldfield with only the Main Reef Series missing that has proved so seductive as to lead to so much money being spent in prospecting. Almost every geological authority has been enticed into writing encouraging reports at one time or another, but always when followed by prospecting operations the results have without exception proved disappointing. The Consolidated Gold Fields of South Africa, Eckstein & Co., the Free State Banket Development Co., Ltd., have all during the present year been induced to spend considerable sums on different properties in this field, but all have stopped work, on the conviction that it is impossible to find the Main Reef Series within their areas, although they represent a length of outcropping Witwatersrand formation over a distance of about forty miles. To prospect the rest of the area showing outcrops of the Witwatersrand beds another company has recently been floated in London under the title of Free State Rands, Ltd., with a nominal capital of £300,000, and has commenced boring operations. Whether this company will meet with more success than its numerous predecessors in the same field remains to be seen. The fact is that the beds hereabouts are much more disturbed by the elevation of the granite boss than the same beds on the Rand; at the surface where exposed they are generally overtilted, while the Main Reef horizon, where the only payable reefs occur on the Rand, is occupied by huge dikes of diabase, and all attempts to find any conclusive evidence of the presence of the Main Reef Series have hitherto resulted in failure.

The Origin of Rocks

The geologist divides rocks into three general classes—igneous rocks, originating from the molten magma forced upward from the bowels of the earth, such as granite and the various lavas; sedimentary rocks, consisting of disintegrated particles of the igneous rocks which have been reformed into rocks, such as sandstone; and metamorphic rocks, consisting of igneous or sedimentary rocks whose composition has been greatly changed by intense heat, chemical action, or other causes, as for instance, a limestone that has been changed to marble.

Sedimentary rocks, as stated in the geologic atlas of the United States Geological Survey, are usually made up of layers or beds which can be easily separated. These layers are called strata, and rocks deposited in such layers are termed stratified. The surface of the earth is not immovable; over wide regions it very slowly rises or sinks with reference to the sea, and shore lines are thereby changed. As a result of upward movement marine sedimentary rocks may become a part of the land, and most of our land areas are in fact occupied by rocks originally deposited as sediments in the sea.

Sandstone is perhaps the simplest example of a sedimentary rock. Obviously sandstone was once sand, and again each grain of sand was once a part of some older rock. This sand was first eroded and then deposited and either subjected to great pressure by overlying masses, perhaps thousands of feet thick, or cemented together by chemical solutions. Where the stone was formed by simple pressure it contains a large proportion of open spaces, and thus becomes an ideal water-bearer. Some sandstones will carry as much as 350 cu. in. of water to the cubic foot of stone. In other varieties the interstices may have been filled with cementing material so that the rock may be for all practical purposes almost as dense as granite.

Rand Gold Production

The official returns for March issued by the Government Mines Department fully confirm those of the Chamber of Mines, but may be taken as more accurate, inasmuch as they are supposed to include all gold actually produced not declared, as is the case with the Chamber of Mines where it is the general custom for the mines to hold some portion of the actual gold output in reserve. Seeing that the March output was a record one for these fields, it may not be amiss to give the different districts and their contribution to the record yield which were as follows:

	Ounces.	Value.
Witwatersrand	651,366.310	£2,766,828
Klerksdorp	2,340.040	9,939
Ottoshoop	131.130	557
Pretoria	37.464	159
Barberton	7,372.565	31,318
Pilgrim's Rest	12,029.888	51,099
Pietersburg	326.290	1,386
Heidelberg	5,190.040	22,046
	678,793.938	£2,883,332

The above represents the output from 101 mines, of which 64 only were at work on the Rand, the remaining 37 being scattered over the different parts of the Transvaal. It has already been explained that the starting up of a portion of the big mill at Randfontein contributed largely to the March output being a record one, but in the event of labor continuing plentiful even this large output will soon be left behind, and it is predicted that before the end of the present year the gold output of the Transvaal will be materially increased.

Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

GLUE to resist boiling water is made by dissolving separately in water 55 lb. glue and a mixture of 40 lb. bichromate of potash and 5 lb. alum. Mix as wanted.

RUBBER TUBES can be preserved and prevented from drying and becoming brittle by being coated with a 3% aqueous solution of carbolic acid. If they have already turned stiff and brittle, they can be rendered soft and pliant again by being placed in dilute ammonia.

A GOOD CEMENT for iron and marble, which will stand heat, is made by dissolving first one pound of water glass and then one pound of borax in three pounds of water. With the solution make a paste of two pounds of clay and one pound of barytes, first mixed dry.

TO LUBRICATE plug-cocks and prevent them from leaking, use 2 parts of tallow and 1 part of beeswax melted together; stir thoroughly, strain, and cool. Glass stoppers may be made tight by melting together equal parts of glycerine and paraffine, and applying the mixture.

AN INK for writing on glass, celluloid, and metal may be prepared by dissolving 20 parts of rosin in 150 parts alcohol, and adding to this, drop by drop, stirring continuously, a solution of 35 parts borax in 250 parts water. This being accomplished, dissolve in the solution sufficient methylene blue to give it the desired tint.

SCREWS may be prevented from becoming fast by anointing them with a mixture of graphite and soft tallow. They will then remain unrusted and unaltered for years. A screw rusted in may be removed by placing the flat extremity of a red-hot rod of iron on it for two or three minutes. After the screw has heated and cooled it will turn easily.

SHARP and full impressions may be produced on figured patterns if all the deep recesses in deep-figured dies are vented to allow the air to escape when the blow is struck. This will do much to obtain perfect impressions, and requires only half the force that is necessary in unvented dies. This is not known in many shops and consequently this little air costs much in power and worry.

TAILING from mining cannot be allowed to escape into a stream to the detriment of one working below. Mining claims are taken subject to right of way for ditches or canals "constructed by authority of the United States." The fact that débris is deposited on a lower proprietor's land is a clear violation of his rights. In a given case it may become a nuisance and may call for and receive injunctive relief. Priority of location does not enter into the matter.

TO DROP STAMPS at the rate of 90 drops per minute, with an 84-in. pulley on the cam-shaft, a 46¼-in. pulley on the counter-shaft, and a 28-in. pulley on the engine, the fourth pulley must bear the following relation to the speed of the engine:

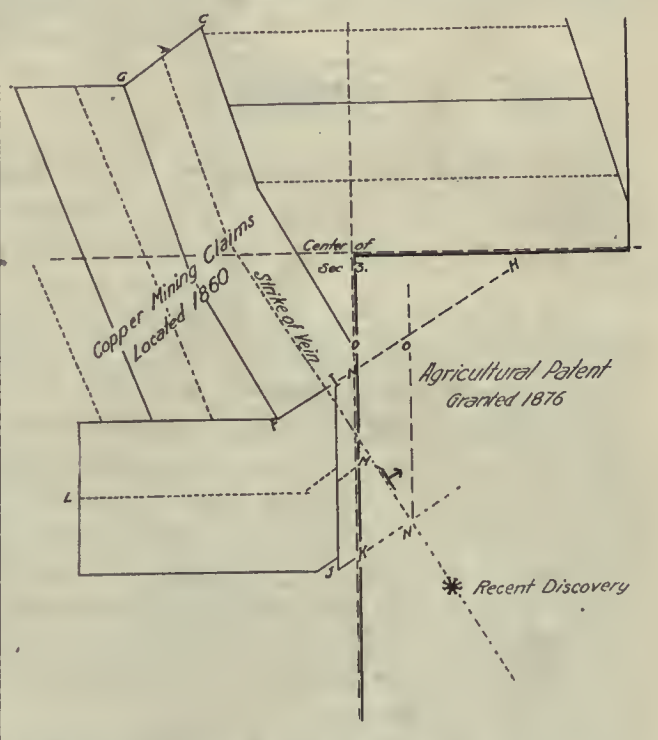
$$\frac{45 \times 84}{46\frac{1}{4}} \times x = \text{speed} \times 28.$$

In other words, the diameter of the fourth pulley in inches is approximately one-third the number of revolutions of the engine per minute.

TO UNITE rubber and leather, roughen both surfaces with a sharp glass edge; apply to both a diluted solution of gutta percha in carbon bisulphide, and let it soak into the material. Then press upon each surface a skin of gutta percha 0.1 in. thick between rolls. The two surfaces are now united in a press, which should be warm but not hot. This method should answer in all cases in which it is applicable. The following prescription covers cases in which a press cannot be used. Cut 30 parts of rubber into small pieces, and dissolve it in 140 parts of carbon bisulphide, the vessel being placed on a water bath at 30°C. (86°F.). Further, melt 10 parts of rubber with 15 of rosin, and add 35 parts of oil of turpentine. When the rubber has been completely dissolved, the two liquids may be mixed. The resulting cement must be kept well corked.

ALUMINUM is used in constantly increasing quantities in the motor-car industry, combining as it does both lightness and stiffness. It is used in making crank cases, gear boxes, carburetors, radiators, and dash-boards, besides in smaller ways. Its use in this comparatively recent industry is of interest, and especially so is its application in the newborn art of aviation, where the same qualities of lightness and stiffness again recommend it. In castings it has been found advantageous to alloy aluminum with copper, zinc, or nickel, which increases its strength and makes it easier to work. The prevailing low prices of ingot aluminum have resulted in a greatly enlarged demand for the metal for such work. The principal demand for such castings has come from automobile builders. The users of brass castings, especially the manufacturers of electrical apparatus, have been gradually changing from brass to aluminum castings, and for some purposes aluminum castings have been substituted for iron castings.

AGRICULTURAL entries on public land are made subject to accrued rights, and consequently the vein of a location older than the agricultural entry or patent may be followed into agricultural land, provided apex rights accrue in regular form. In the case cited below this would not seem to be true on the statement given. The vein A N upon which recent discovery was made could be followed under one corner of the land under rights belonging to the claim C D F G, assuming the dip to be as indicated



by arrow. Extralateral rights are limited by the end line F H projected. Since the claim N I J K was presumably located on another vein L M, and since, though not as drawn, the vein A N crossed both side lines and these hence become end lines, no additional rights under the agricultural land would seem to accrue. If in fact the location prior to agricultural entry extended to N O and beyond, there would be room for claim to work ore in the vein A N under the ground N K O N. It should be remembered that no rights accrue to the old locations unless they have been in fact kept in good standing since before agricultural entry.

Discussion

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

Surface Indications of Ore-Shoots in Depth

The Editor:

Sir—The original contribution of W. H. Storms, in the issue of October 22, 1910, on 'Surface Indications of Ore-Shoots in Depth' has drawn out interesting letters from other observers, and much of the evidence presented is confirmatory of the original dictum: that there is an apparent relation between the surface topography and the position of underlying ore-shoots.

The revival of interest in the Comstock Lode by the discovery of an important orebody in depth in the Mexican mine, through prospecting intelligently directed by a capable mining engineer, once more draws attention to the remarkable work of F. von Richthofen, the earliest writer of note, excepting Clarence King, upon the Comstock ore-occurrence. There is given herewith from his 'Conclusions', as stated on page 113 of the book 'Sutro Tunnel, Nevada, 1865', the following paragraphs which bear directly upon Mr. Storms' observations:

"4. In the northern part the vein is, at the levels explored to the present time, invariably poor where it passes a ravine, as in the Ophir, Central, and Mt. Davidson ravines, and the one which divides Mt. Davidson from Mt. Butler. But in the southern part the ore continues in the ravines. (Kentuck and Seg. Belcher mines.)

"5. The richest portions are south of each ravine crossed by the vein."

The exceptions to the rule noted in 4, where it is stated that the ore was continuous in the ravines in the Kentuck and Seg. Belcher mines, proved to be the only exceptions to the rule in the South End mines, and of these only the Kentuck body proved to be of magnitude.

The sketches herewith, illustrating this, were made from sketches by John and Charles Hoffman, in 1865, and in 1870. The typical section through the Comstock Lode, and the plan of the faulting of the district, are from J. A. Reid's paper, referred to subsequently.

Von Richthofen's observations and deductions were as of 1865, when no mine opening on the Lode was deeper than 900 ft., when the east-dipping character of the Lode had not yet been determined, and when only the distinctly surface bonanzas had been mined. And while his remarkable predictions as to the existence and position of deeper-lying bodies under different conditions were fulfilled later, these subsequently found bodies have no relation to the surface ores, and their position with respect to the ravines cannot be closely followed because of being one and one-half miles eastward in lateral position. Von Richthofen's prediction as to the deeper ore was in these words:

"* * * it is also probable that repeatedly in following the Lode downward branches will be found rising from its main body vertically into the hanging wall * * * such eastern bodies might carry richer ores than the average of the main portion of the vein."

From the foregoing it is apparent that the idea of a relation between ore position and surface topography is not a new conception, but is a generalization deduced in this instance 46 years ago. Mr. Ransome, in his letter in this discussion published in the issue of May 20, states that the conditions involved in sizing up ore deposits generally make it a complex problem, and to establish an invariable rule for the guidance of prospecting is out of the question. He instances notable exceptions to Mr. Storms' hypothesis. It is believed, however, that sufficient consonance does exist in the facts reported to make generalizations safe, particularly where the conditions are parallel.

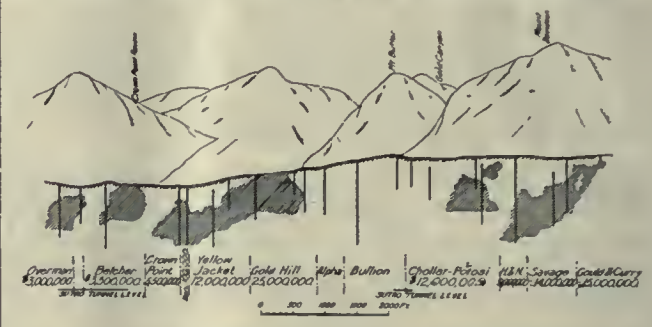


FIG. 1. ORE STOPED TO 1870, COMSTOCK LODE.

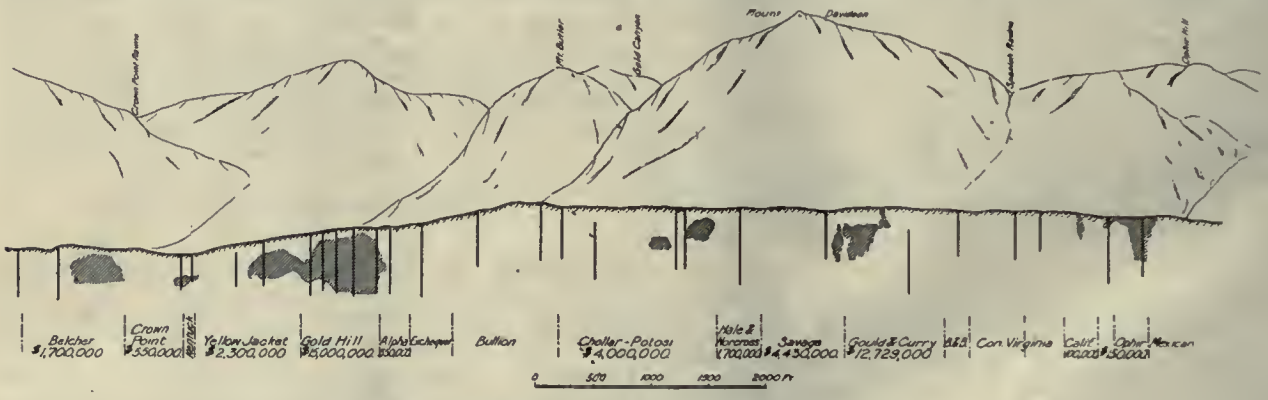

FIG. 2. STOPES OPEN PRIOR TO 1866, COMSTOCK LODE.

In the instance of the Comstock, J. A. Reid has shown (Bulletin 10, Vol. 4, Dept. Geology, Univ. Cal.) that the ravines coursing the east face of the Virginia Range in the immediate vicinity of Mt. Davidson, against which the Lode, occupying the great fault-fissure, lies, are the axes of cross faults, illustrated in Fig. 3. He has demonstrated this beyond questioning, and demonstrated also that the surface erosion along the small streams occupying these ravines has been negligible in amount, hence could not have torn away the portion of possible pay-ore which might have occupied the vein in the ravine site. On the allowable assumption that, in the secondary or commercial-ore forming period, the mineral-bearing solutions coursed upward through the cross-faults, the depositing of the minerals out of these solutions (the ore-making) must actually have occurred in the main fault-fissure, or the Lode proper where the conditions favorable and necessary for such occurrence were met. All writers have recognized that there were two distinct periods of vein-forming in the Comstock; the first filled the fissure with the great masses of low-grade, or of barren, quartz, which are encountered in every mine on the Lode; the second period marked the fissuring of these quartz masses and the deposition within same of the commercial ore. The cross-faulting was evidently subsequent to the first or quartz-forming period, owing to the small amount of displacement of the walls.

excepting in Bullion ravine, where the diorite mass of Mt. Davidson was thrown in juxtaposition with the andesite mass to the south, and to the fact that there was no measurable displacement of the main lode. Reid has shown that the hot mine waters in circulation in depth at this time (samples from 2250-ft. level, C. & C. shaft, and temperatures from 116° to 170°F.) are highly alkaline and carry gold and silver to the extent of 0.298 mg. and 2.92 mg., respectively, per ton of solution, while the surface waters issuing from the Central Tunnel (an old adit pene-

FIG. 3. PLAN OF COMSTOCK LODE, SHOWING FAULTS.

trating the croppings at some 300-ft. depth) carry the same minerals to the extent of gold, 4.15 mg., and silver, 188 mg., per ton of solution. This statement of fact indicates, though it does not necessarily prove, the genesis of the ore deposit, and the origin of the solutions is in all likelihood in the cross-faults.

If the steps for establishing an hypothesis as a scientific

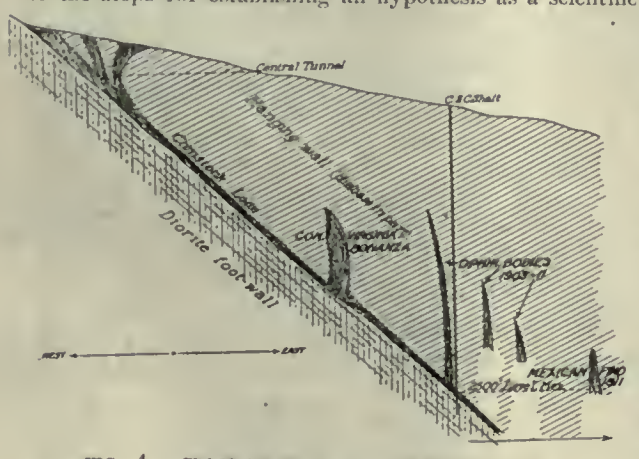

FIG. 4. CROSS-SECTION OF COMSTOCK LODE.

truth be the process of working outwardly from a single fact, accurately established, to a wider generalization, there is more to be gained by moving in the direction of working out concrete examples. Types of deposits admittedly exist, and if a generalization can be applied to a distinct type, so much will have been gained. The argument, then, is to multiply the concrete examples which fit this particular hypothesis, and additional light will be unfolded in due course.

J. H. G. WOLF.

San Francisco, May 22.

The Editor:

Sir—I am very much interested in the discussion of 'Surface Indications of Ore-Shoots', having made this subject a special study for over twenty years. In a personal examination of the surface indications of over 500 ore-shoots in the United States, Alaska, Mexico, Australia, and Tasmania I have found that by far the greatest number, especially bonanza ore-shoots, outcrop along the strike of the vein on hills or rising ground, rather than in gulches. The reason in general, I think, is that the enclosing rock of ore-shoots is harder than the barren portions of the vein, and has resisted erosion more than the softer part.

M. K. RODGERS.

Seattle, June 5.

Secondary Enrichment of Gold Deposits

The Editor:

Sir—In the June 3 issue of the *Mining and Scientific Press* there is an article on the secondary enrichment of gold deposits. I would like to call attention to what I would call second deposits. All through the San Juan section of Colorado there are a great many large veins in which the vein filling is largely rhodonite. This rock when broken in the mine is often very attractive looking, but I do not know of one case in which the rhodonite contains valuable metal, yet some of the most profitable mines in the district are in these veins. These ore deposits I would call second deposits; in distinction from the deposits made valuable by secondary enrichment, for this reason: There is nothing in the appearance of the vein rock to indicate that the primary deposit has been enriched. The pay ore ore seems to be deposited alongside of the rhodonite, but easily separated from it, as if the primary vein had been opened along one wall by faulting, thus giving an opening for a second deposit. In some cases the primary vein has been shattered in places, which has allowed the formation of the second deposit within the primary vein instead of along the wall. This second deposit is sometimes gold ore and sometimes silver. When the second deposit is silver ore it is almost always in the form of ruby or brittle silver.

One of the best examples of this kind of deposit is what is known as the Smuggler-Union in San Miguel county. This vein was originally a rhodonite vein and extended through the Bullion location. It was faulted by the Memphis vein which crossed it nearly at right angles, the fault throwing the Bullion end of the vein about 50 ft. to the west. From the Memphis north through the Union, Smuggler, Sheridan, and Mendota locations to the top of the range, the vein has the second deposit, while from the Memphis south through the Bullion and other locations, there is only the primary or rhodonite vein.

The largest vein in San Miguel county is, I think, the one formerly called the Big Elephant vein. The Montana mine is at the northwest end of this vein, and the Argentine and Red Cloud (now owned by the Tomboy M. Co.) are on the southeast end. In places in this vein on the Shamrock location I have measured 16 ft. in width of rhodonite. The large veins that cross Mineral Point and Poughkeepsie gulch in San Juan county belong to this class, and pay deposits should be looked for in these veins where the primary vein has been faulted or shattered. I am not familiar with the late workings of the Camp Bird in Ouray county, but am inclined to think that there is reason to class this as a second deposit. Secondary enriched deposits usually have the surface metals leached out and re-deposited below. What I call second deposits have their richest ore on top, and the rich ore does not usually extend to a greater depth than 1000 ft. These second deposits are always in or along manganese or rhodonite veins. The rhodonite which forms the vein filling of these veins is close-grained and massive, and the valuable metals do not always appear to have been leached out, yet it seems to have been influential in causing these deposits, because the richest second deposits occur in those veins in which the primary deposit of rhodonite is the largest. I am not prepared at present to present any theory explaining these phenomena, but submit the facts for discussion.

H. W. REED.

Salt Lake City, June 9.

RHODONITE is a silicate of manganese, $MnSiO_3$, but the manganese is often partly replaced by Fe, Zn, or Ca. It is a brownish to bright red mineral, occurring in fine-grained or cleavable masses and disseminated grains, often coated with a black oxide.

Special Correspondence

JOHANNESBURG, TRANSVAAL

East Rand Prop. Meeting.—Profits for Year.—Decrease of Yield.—Improvements in Methods of Working.—Second-Stage Hoisting.

The principal feature of interest during the week has been the East Rand Proprietary Mines meeting, adjourned several times to enable the chairman of the company, Sir George Farrar, to attend. The East Rand Proprietary Mines was the first important amalgamation on the Rand in which the outcrop mines joined with the extensive deep-level properties containing the Main Reef Series. Since this amalgamation several others have been arranged, notably the Crown Mines Ltd., which in March succeeded in displacing the E. R. P. M. from its proud position at the head of the gold producers of the world, which it had occupied ever since the amalgamation took place.

The chairman announced at this meeting that the profits for the year were £1,249,357, being £9700 less than the preceding year, but the usual dividend of 40% had been paid, and moreover the finances of the amalgamated concern had been put on a sound footing by the increased issue of debenture capital during the year. To procure these results no less than 2,126,334 tons of 7-dwt. ore by assay has been crushed, the actual recovery being 6.5 dwt. per ton, which made the total yield 691,860 oz. of fine gold. Broadly speaking, they had recovered 27s. 3d. per ton at a cost of 15s. 6d. per ton, so that their profit was 11s. 9d. per ton. Some idea of the extent of the underground workings may be gathered from the fact that they reach over 6000 ft. on the dip; the vertical shafts of the Angelo Deep mine connect with the deepest points of the workings, ensuring a perfect system of ventilation. The results of the year's operations, however satisfactory, do not appear to have come up to anticipations, so far as profits and dividends are concerned, and it will be remembered that a similar experience was had at the Crown Mines, a similarly amalgamated concern. At the East Rand Proprietary Mines, a falling off in grade in the Cason section, and the absorption of gold by a new recovery plant are blamed for this disappointment; and seeing that the tonnage crushed during the year has increased from 157,000 to over 200,000 for somewhat less profits, it is clear that the yield has fallen. The actual recovery was 92.85%, obtained from the different sources in the following proportions: Mill, 53.97%; sand, 31.32; slime, 13.51; and from by-products, 1.20%. Out of £17,000,000 total value of gold produced by the East Rand Proprietary Mines, $5,000,000 has been distributed to shareholders, and as the scale of operations increases it appears probable that the dividends payable to the shareholders will also increase.

Although the amalgamation of different small producing mines, as in the case of the East Rand Proprietary Mines and the Crown Mines does not seem to have immediately produced the anticipated improvement in the working results, there can be no doubt that better results must eventually follow. Last year's experience at the East Rand Proprietary Mines goes to show that where ore values vary as they do on the Rand, small single mines are bound sooner or later to get into trouble, but by being amalgamated can draw on other sections of the amalgamated concern and so spread the risks over larger areas and in the end produce uniform results. Another interesting feature arising from these amalgamations is that of large-scale working, and the eventual reduction of working costs to the lowest limit that must follow; without which it will become impossible to work some of the very deep sections of the Rand goldfield. Both the East Rand Proprietary Mines and the Crown Mines, especially the latter, extend to where the reef series lie very deep, and both are preparing to tackle these deeper areas in a workmanlike manner. For instance, large dimensioned levels are being constructed underground fitted with modern systems of haulage, and conveyance of ore to the shafts will be concentrated so as to be carried out in the most economical manner. The methods of handling large quantities of ore on the Rand have been much discussed of late, and it seems likely that this method will be generally adopted. At the East Rand Proprietary Mines the idea seems to be to construct this main level right across the property from east to west at a point something like 4000 ft. deep on the incline, where hauling can be most efficiently and economically carried out as a first-stage hoisting. Of course all the ore above this level will be dropped to that level at convenient points; the lower ore will be hoisted to that level, so constituting a system of second-stage hoisting. Other deeper main levels will also be constructed and equipped, and it is hoped thus to overcome the present hoisting and mining difficulties on the Rand.

MEXICO

Repair of Railroad Lines.—Conditions in Guanajuato. Suspension of Work at Cinco Minas.—Option on the Alvarado M. & M. Co.—Report of Mexican Light & Power Company.

Now that hostilities in Mexico have ceased, the railroad lines damaged by the revolutionists are being rapidly repaired, and normal traffic conditions are expected shortly. The revolutionists stopped train service on nearly 4000 kilometres of the Government merger system, and in addition cut the Southern Pacific lines in Sonora and Sinaloa, the Mexico Northwestern lines in Chihuahua, and the Mexican Railway between Mexico City and Veracruz. The re-establishment of railroad traffic will do much toward restoring the mining industry to its former basis. It is probable that strong measures will have to be taken to stop bandit raids, as brigandage has been a natural development of the disturbed conditions, and some bands undoubtedly will attempt to continue operations. The theft of bullion worth ₱35,000 from the San Jose de Garcia camp in Sinaloa was recently reported. The suppression of brigandage is receiving the attention of the provisional government, and it is planned to organize rural forces from the ranks of the revolutionists, and to entrust to them the work of wiping out the plundering bands. It will not be surprising if the mining investments checked by the political upheaval in Mexico will now wait on the coming elections. The triumph of the Madero revolution and the end of the Diaz government has left the Mexican people facing many new problems, and they will be required to prove their ability to handle them.

George W. Bryant, prominently identified with several Guanajuato enterprises, states that operators in the Guanajuato district have been interfered with but little. When the revolutionists became active in that state the labor supply was affected to some extent, but only for a short period. When the Mexican Express Co. declined to assume any risk in the handling of bullion, the Guanajuato companies sending out bullion insured the shipments with an American concern. None of the bullion shipped was lost. In the Zacualpan district of the State of Mexico disturbed conditions resulted in the shutting down of practically all the mines. The Seguranza Mining Co., the most important concern of the district, suspended all mining and milling operations. The managers of the principal mining companies of the Pachuca district have signed a letter highly complimenting and thanking Col. Gabriel Hernandez, the commander of the Madero forces in the State of Hidalgo, for his energetic suppression of lawlessness in Pachuca. Operations in that district have been but slightly affected.

According to late reports, more than 30 men were killed in an attack on the smelter of the American Smelters Securities Co., at Matehuala, State of San Luis Potosi. The smelter employees made a demand for higher wages and shorter hours, and when the management refused to accede to the demand an attack on the smelter was organized. The arrival of a Maderista leader at the head of an armed force is believed to have prevented serious damage to the plant and the looting of the town. Order was finally restored.

The Cinco Minas Co., of New York, has suspended work at the Old Cinco Minas in the Hostotipaquillo district of Jalisco. Control of these properties may change hands, negotiations to that end having been recently opened. The Cinco Minas were purchased by the Marcus Daly interests early in 1910, after a period of development under an option, and have been controlled by them since that time. The Magistral-Ameca Copper Co., a Los Angeles organization owning the Magistral mines and concentrating plant in the Ameca district of Jalisco, will be able to resume shortly, it is stated. Several months ago the company arranged to place a large block of stock with French and Mexican capitalists, the money to be used in enlarging the concentrating plant and carrying on extensive development. The revolution interfered with the plans, and operations were suspended. Now it is said that more money than originally arranged for is ready for the enterprise. The new capital will be principally French.

Representatives of strong financial interests have asked for an option to purchase 450,000 shares of the Alvarado Mining & Milling Co., operating in the Parral district of Chihuahua, at $5 per share. It is stated that the option probably will be granted, and that each stockholder will be given an opportunity to participate in the sale to the extent of one-half of his holdings. The Mexican Light & Power Co., the Canadian concern owning the big Necaxa

CINCO MINAS, JALISCO, MEXICO.

power enterprise, and furnishing current to Mexico City and the El Oro and Pachuca mining districts, shows gross earnings for the first four months of this year of ₱2,710,255, an increase of ₱616,109 compared with the same period of 1910. However, the operating expenses, ₱956,605, represented an increase of ₱454,153. The net earnings were ₱1,753,650, an increase of ₱161,956.

NEW YORK

EFFECT OF DECISION.—THE COPPER MERGER.—STRENGTHENING OF MARKET.—ANNUAL MEETING OF OHIO COPPER.—ANNUAL REPORTS OF COPPER PRODUCERS.—PRICE OF TIN.

Broadly speaking, the prevailing feeling in the Street is one of disappointment. The Supreme Court decision had, for many months, served as an excuse for the absence of the public. It was only logical, therefore, that every effort should be made to construe the decisions as encouragingly as possible. The feast was spread and the public bidden, but the occasion was not a success. Perhaps the most significant and most important utterance concerning the situation is that of E. H. Gary, chairman of the board of the U. S. Steel Corporation. Socialists and radicals of all degrees have been clamoring for governmental control of the large corporations. It is therefore a startling instance of the meeting of extremes, when the head of the Steel Trust declares that governmental regulation of prices is necessary and, from the view-point of the corporation, desirable. The testimony of Mr. Gary will play a large part in the coming political campaigns and 'willy nilly' the regulation of the big combinations is to be the real issue.

The copper merger must be considered as definitely sidetracked for the time being. There could hardly be found now any legal talent bold enough to attempt the creation of the long-talked-of combination. For the present, and apparently for some time to come, the factors in the copper metal market must content themselves with such coöperation as they can secure one from the other. This spells hard sledding for some of the high-cost producers and possibly suspension of dividends by some that have been running close to the line between profit and loss.

The metal market has been firm for the past few days, in expectation of the fairly good report which was given out by the Producers Association on June 8. Production in May was 126,962,544 lb., being an increase in output (in round numbers) of 9,000,000 lb., larger than any month of the current year save March, when the total production was 130,532,080 lb. The encouraging feature during May was the increase in domestic deliveries from 52,407,650 lb. in April to 64,543,963 lb. in March. Export deliveries for May were 61,978,557 lb., as against 62,129,599 lb. in April, a slight decline. The selling agencies have inquiries now in hand that apparently insure increased demand for home consumption for the next sixty days, while, on the other hand, no further increase in output is anticipated. This improved condition, present and prospective, has stiffened the price of copper metal to 12½c., with a rising tone. Copper shares are neglected market wise. Several of the most active traders have changed from the outside market to the floor of the Stock Exchange, and have in each instance lost in activity by the transition.

Contrary to expectation, the annual meeting of the Ohio Copper Co., instead of marking the end of the Heinze control, was the occasion for the apparently complete extinguishment of all opposition to Mr. Heinze. Three new members of the board chosen are all Heinze adherents. The financial statement in which the Eastern market is somewhat interested was postponed, awaiting, it is said, the completion of the sale of the rest of the bond issue. That is one thing that is spared to Heinze stockholders, they are not forced to analyze long financial statements—or short ones either, for that matter. The meeting of the United Copper Co. which was to have been held this week has been postponed. Mason Valley, the Gunn-Thompson property at Yerington, Nevada, is one of the copper issues which is about to forsake the open market for the shelter of the Stock Exchange. The property is being equipped and developed as rapidly as possible.

The annual reports of the Amalgamated, Anaconda, United Metals, and the International Smelting & Refining companies have come in for a great deal of keen analysis. The market position of Amalgamated, paying $2 per year and selling for $67 per share, invites constant attention. The weakness from the income point of view is obvious. This is offset somewhat by the accumulation of surplus. Amalgamated receives $2 per share on 3,045,000 of Anaconda, and pays out $2 per share on 1,538,879 shares of its own stock. This resulted in a net surplus for the year ending April 30, 1911, of $2,971,000. Ordinarily an increase in dividends might be expected, but Amalgamated has outstanding some $5,000,000 in notes issued in the pur-

chase of the Clarke properties, and also some $12,500,000 in notes issued in connection with the purchase of the United Metals Selling. Both the mining properties and the Selling company show net returns above expenses and carrying charges on the notes, but these requirements will probably absorb the surplus for the next eighteen months unless these obligations are in some way refunded, or there is a radical improvement in the copper market.

Greene-Cananea was evidently undisturbed by the latest unpleasantness in Mexico; the production for May was larger than for any month of the current year, being 4,098,000 lb. of copper, 119,900 oz. of silver, and 552 oz. of gold. The reports of the Butte Coalition will hereafter be very short. It will, upon the dissolution of the Alice Gold & Silver, hold 517,566 shares of the Anaconda, 3000 shares of International Smelting & Refining, and has some $3,840,000 cash on hand, making a book total of $15,140,000. The smelting stock is carried at par, whereas the market is $130, Anaconda at a little above $21. The grip of the English operators who have engineered a corner in tin is tightening. Spot tin is quoted around $1040 per ton, which is very close to a record price for the metal. The market situation is stimulating production, and increased output is expected.

VALDEZ, ALASKA

THE CLIFF MINE.—HIGH-GRADE ORE.—DEVELOPMENTS OF THE VALDEZ M. CO.—RICH ORE IN WILLIAMS-GENTZLER.—OTHER PROPERTIES.

The Cliff mine was first opened up in 1910, a small mill was installed in July. It is considered to be the best mine in the camp by reason of the fact that it is on a producing and dividend paying basis. The work consists of about 2000 ft. of shafts, drifts, cross-cuts, and tunnels. The ore is extremely rich, and the mine has paid up to date $160,000 in dividends taken out in less than a year. The mine is developed by three tunnels, and a shaft from tunnel No. 2, the depth attained being about 600 ft. below the back of the mountain, and about 120 ft. below the water-level. The ore has been found on all the levels, varying in width from a foot to as much as six feet. The ore below the water-level carries sulphides and is extremely rich. The mine is a veritable jewelry shop, as rock showing abundant free gold can be found in many portions of it. In the raise between adit No. 2 and adit No. 3, there is a body of ore 6 ft. in width, which, it is stated, runs $433 per ton, on an average. This is phenomenal, but as specimen rock could be picked up from almost any portion of the face, the sampling is no doubt correct. Quite a little jewelry has been made from this ore, it being adapted for this purpose, as the broad bands and seams of gold contrast well with the pure white quartz.

The estate of the Valdez Mining Co. has been developed by means of a tunnel along the foot-wall of the vein for a distance of 200 ft., and the vein has been cross-cut every 20 ft. The vein is from 7 to 15 ft. wide, and has been proved continuous, so far as developed. The entire body is of a shipping grade, and average values of $40 per ton have been obtained. Rock showing free gold is a common occurrence in the mine. Some of the most spectacular ore ever found in the district comes from the Williams-Gentzler property on Mineral creek. The vein is about 2½ ft. wide, and for 45 ft. in length where it has been opened up pieces of rock liberally sprinkled and cobwebbed with gold can be taken from almost any portion of it. Some of the rock assays as high as $10 per pound. This property was recently sold to J. M. Hall, former mining partner of ex-President Zelaya, of Nicaragua, for a consideration stated to be in the neighborhood of $100,000.

The Mineral Creek mine on upper Mineral creek was purchased last fall by the owners of the Cliff mine. The vein is about 3½ ft. wide, and it is estimated that there is over $50,000 worth of ore in sight, although little work has as yet been done. The plans of the company contemplate active development work and the erection of a mill. The Seely-Davis mine is situated over the hill from the Cliff mine, and is said to have the extension of the Cliff lead. The property is developed by adits, and the vein varies from 2 to 3½ ft. Some showy specimens have been obtained from this mine. There are a number of other properties on which work is progressing and which have made rich discoveries, such as the Vancouver-Valdez, High Grade group, Black Diamond, Palmer group, Suessdorf-Devinney, Martin property, and others. There are about 300 men at work in the district.

COBALT, ONTARIO

ACTIVITY AT COBALT.—RECENT FINDS.—DEVELOPMENTS IN GOWGANDA DISTRICT.—CLOSE OF LITIGATION.—SHIPMENTS FROM COBALT.—PROGRESS AT THE MINES.

At Cobalt activity has been fairly resumed and shipments are increasing. Another good find has been made at the Beaver at 350 ft. in the main vein, which shows 8 in. of high-grade ore. This is regarded as proving high silver content through four levels to the surface. The Ophir has excellent showings on the 200 and 300-ft. levels in addition to an orebody from which considerable high-grade ore has lately been taken at the 100-ft. level. A shaft is to be put down on the big smaltite vein recently uncovered on the south end of the property. The Green-Meehan is again on the list of shipping mines, having sent out a car of high-grade ore taken from the 100-ft. level. Several new finds have recently been made and good ore is being taken out below 150 ft. The rehabilitation of the mine will probably stimulate other enterprises in the North Cobalt district. The Cobalt Lake is making good progress in the installation of the 20-stamp mill, which is expected to be in operation by August. The management states that a two-year supply of ore is in sight.

The Millerett and Miller-Lake O'Brien mines in the Gowganda district will make shipments this summer notwithstanding the bad condition of the roads, by which mining industry in that district is badly handicapped. The Millerett mill will be completed in July, enabling the company to ship concentrates as well as high-grade ore. The Boyd-Gordon in the same district has found on the 75-ft. level a vein 2 in. wide which yielded high-grade ore at the 40-ft. level.

The three-year litigation over the ownership of the Sterling mines, embracing three or four hundred acres in the Cobalt area, has been brought to a close by a decision of the Imperial Privy Council confirming the judgment of the Canadian courts in favor of William Marshall of Toronto and the Grey's Siding Development Co., and dismissing the appeal of the Drummond Mines Ltd. and the Montreal Trust Co. The property was bought by Marshall from Robert Gilmour of Sudbury, who subsequently sold it again to the Drummond Mines, claiming that the terms of his agreement with Marshall had not been fulfilled.

Shipments from Cobalt are increasing, the output for May being 1950 tons. There is a noticeable decrease as compared with last year's shipments, partly on account of the power shortage during the earlier months of the year, and partly owing to the increased output in the form of concentrate and bullion. Arrangements have been completed for the treatment of ore from the Crown Reserve and Kerr Lake mines at the Nova Scotia mill, which is the only one in Cobalt using the cyanide process. The capacity of the mill is being nearly doubled, so as to permit of the treatment of 200 tons of ore per day. The contract for an aerial tramway for the conveyance of the ore has been let to an American firm for about $15,000. Operations are to be resumed at the Waldman on the Gillies Limit, where the shaft is being unwatered. Trenching is being carried on in the hope of finding new veins. The Nipissing will put down a shaft to the depth of 1000 ft. on the No. 64 vein to solve the much-discussed question as to the persistence of the ore at depth. The Kerry mine has been unwatered and operations resumed at the 350-ft. level. A fire on June 1 destroyed the power plant of the Nancy Helen, causing a loss of $16,000. The mine has been closed down for some time. La Rose is opening up a third level in its main shaft

at a depth of 270 ft., the deepest point attained in the workings. The Beaver shaft is down to 420 ft. and a station has been cut at 400 ft. The vein on the 300-ft. level runs from 6 to 8 in. of high-grade ore. The steady increase in the price of Beaver stock is in marked contrast to the dullness in most of the Cobalt issues—largely due to the Porcupine boom. The Rochester will put down its main shaft to 400 feet.

BUTTE, MONTANA

COMPRESSED-AIR HOIST IN USE AT MOUNTAIN VIEW MINE.—THREE ELECTRIC-DRIVEN AIR-COMPRESSORS.—OTHER SHAFTS BEING SIMILARLY EQUIPPED.—MAY PRODUCTION OF THE ANACONDA.

With an expenditure of over $3,000,000, the Anaconda Copper Co. has demonstrated the feasibility of hoisting ore by compressed air supplied from electric-driven compressors. Over two years ago the company had plans and specifications prepared with the view of putting the plan into practice, and a few days ago it had the satisfaction of seeing the change accomplished. This undoubtedly will result in greatly reducing the cost of production of copper. Those who have been making a study of the subject declare that when compressed air has completely taken the place of steam it will mean a lessening of the cost over one cent per pound. After John D. Ryan, president of the Amalgamated, and some of his officials had worked out their plans, the Nordberg Manufacturing Co. people were called into consultation, and they undertook to construct a plant which would carry out the ideas outlined by Mr. Ryan. To start with, it was necessary to bring electricity from Great Falls, a distance of some 150 miles, to operate the plant, and it was therefore decided to construct a pole-line to this city. No time was lost, and the work was finished last summer. In the construction of this line the greatest care was taken to prevent lightning interfering with the transmission, and the latest inventions along this line were brought into use. While this line was being built skilled men were at work in the Nordberg factory constructing the operating machinery, and others were erecting concrete and steel buildings and tanks for the storage of the machinery and the proper operating of the plant at Butte. Last July everything was in readiness for the installation, and piece by piece the Nordberg company delivered the equipment; and about one month ago everything was in place. Bruno Nordberg, who visited the city several times during the construction, finally came to witness the testing of the compressors. At first some little changes were required, as is usual in the starting of new machinery, and a few days ago the tests were all pronounced satisfactory and the hoisting of ore was commenced. Not a hitch occurred, and today, at the Mountain View mine, ore is being hoisted by the new system with the same ease as when steam was the motive power.

The substitution of air for steam in hoisting operations on a large scale is a new departure in copper mining, and the Anaconda Copper M. Co. should have the credit for starting the system. Ever since work was first started on the plant, mining people all over the country have been watching the progress of the experiment, for an experiment it was considered, even by many who believed in it. That today it is a complete success, and that the Mountain View is hoisting all the ore required, is a source of pleasure and pride to the originators of the system. It means that eventually electricity will play an important part in lowering the cost of the operation of mines, not only in this district, but throughout the country.

The Diamond mine is now being equipped with the same system, and after it is in successful operation, hoisting at the High Ore shaft will be changed from steam to air. The Anaconda company contemplates the using of compressed air for hoisting and electricity for all its mines, pumps, and underground haulage. The fact that all steam boilers will be done away with, and a yearly expenditure of over $2,000,000 for coal will be saved to the company affords some idea of the economy of the change. The plant consists of three compressors, each with a capacity of 7500 cu. ft. of free air per minute. When operated at full capacity the power required to drive the three compressors is 3600 horse-power.

VIEW OF WALKERVILLE, BUTTE, MONTANA.

The Anaconda Copper Co. produced 21,700,000 lb. of copper during May, 200,000 lb. more than the production of April. While it would appear on the face of it that there was an increase of production, investigation shows that there was really a decline of something like 100,000 lb., as the Tuolumne output is included in the Anaconda production, as well as that of the North Butte. In April the Tuolumne had a production of 500,000 lb., and in May a production of about 750,000 lb. The North Butte, which was credited with 2,000,000 lb., had at least 100,000 lb. over that amount in May. It may be stated that while the North Butte and Tuolumne companies are independent concerns, their production is included in the figures given out by the Anaconda company, for the reason that the ore from both companies is treated at the Anaconda smelter.

General Mining News

ALASKA

Juneau District

The Alaska Treadwell Gold M. Co., for the month ended May 15, reports having crushed 72,968 tons of ore in the 240 and 300-stamp mills, and the production of 1436 tons of concentrate. The estimated gross value of free gold recovered was $81,614; value of concentrate, $63,309; estimated total realizable value of product, $140,127. Operating expenses, $88,342; net operating profit, $51,785; construction, $16,318. Yield of ore milled, $1.99 per ton. Stock of ore broken, 13,451 tons; development, 920 feet.

Ketchikan District

The Santa Fe group of claims, at Dolomi, Prince of Wales island, is to be developed this season by A. Adkins, H. Z. Burkhart, and Willis Bryant, the owners. Work previously done resulted in exposing gold ore of high grade.

Prince William Sound

The Seattle Alaska Copper Co. is building a concentrating mill at its mine, on Latouche island. The mine is said to contain a large tonnage of ore assaying 3% copper, and this is to be concentrated in the ratio of 8 to 1. The company has developed water-power.

There is activity in the district lying between Valdez and the Cliff mine, and it is asserted that some development is in progress on most of the claims located. The snow disappeared from this locality about June 1. There is much prospecting along the beach. Valdez-Liscum, Black Diamond, and others are being developed, and each has some ore.

(Special Correspondence.)—The Hemple Copper M. Co. is to drive a raise in ore from the 700 to the 350-ft. adit levels. This will result in opening the mine so that it may be productive. As soon as this work is accomplished the company may build a concentrating mill similar to the one being built on Montgomery bay, Latouche island, as the ores of the two properties are similar.

Valdez, June 1.

ARIZONA

Cochise County

(Special Correspondence.)—The Commonwealth M. & M. Co., owner of the Commonwealth mine at Pearce, has recently completed a plant for the treatment of slime from the tailing pond, but has not placed it in operation, because it was decided to do further work in the mine with the view of developing sufficient ore for a 200-ton mill, instead of a plant of 100 tons, as first decided upon. Having the mill running on ore from the mine, will materially cut down the average cost of the treatment of the tailing as well as the treatment of the ore. In other words, a large tonnage can be handled much cheaper than a small tonnage. Development work up to the present time has resulted more favorably than had been anticipated. It is therefore almost certain that the capacity of the new mill will be sufficient to treat 200 tons of ore from the mine and 100 tons from the tailing pond.

MAP OF ARIZONA.

Pearce, June 10.

CALIFORNIA

Butte County

The Kidd mine, situated at Nimshew, primarily a gold mine, has a body of silver ore, assays of which show $21 per ton. It was discovered in driving a cross-cut to open an ancient creek channel, which is believed to be rich in gold. The silver ore will be mined later. R. P. Holmes and L. Mitchell, of Sacramento, are among the stockholders in the company that owns the mine.

The El Oro Dredging Co., for which W. S. Noyes of San Francisco is manager, is operating two dredges, each having 5-cu. ft. buckets, in Oroville district. The chain of buckets on both dredges is digging to a depth of about 30 feet.

Calaveras County

The Lightner Gold Mining Co., operating at Angels Camp, now has 40 stamps crushing ore, 20 stamps having been started June 1. It is probable that the entire mill of 60 stamps will be in operation before July 1. During May there was hoisted from the mine 2979 tons of ore, and 2802 tons of waste. With 40 stamps dropping, the mill is crushing about 220 tons per 24 hours, the battery screens being 30 mesh. Of the total saving made, about 50% is recovered by amalgamation inside the mortars, 25% on the plates, and the remaining 25% by concentrating tables. The concentrate product is equal to 1½ to 2% of the tonnage of ore milled, and samples about $45 per ton. It is understood that the mill tailing contains 21 to 32c. per ton. Electric power for all purposes is purchased from the Pacific Gas & Electric Co., at $4.50 per horse-power month. The May consumption of power was 25.7 hp. for the mill with 20 stamps operating, and 62.66 hp. for the hoist, air-compressor, surface tramway, and machine-shop. The mine timbers required amount to over 1½ million feet per annum. The vein occurs between a schist hanging wall and a slate foot-wall, and has a dip of about 70°. The mill work is in charge of Jack Mallett, and Caesar Sciaroni is mine foreman. A. M. Younge, secretary for the company, states that other mines at Angels Camp are quite active.

LIGHTNER MILL AND MINE, ANGELS CAMP, CALIFORNIA.

Inyo County

The Arondo mine, in Argus mountains, with a force of 65 men, has a daily output of about 80 tons of ore, which is being crushed and cyanided. Charles E. Anderson is in charge of the work.

Nevada County

The Eagle Bird mine, near Washington, was sold to San

Francisco men, recently, who are to provide new equipment and resume operations. The former owner and vendor was W. M. Wilson, who lost by fire his surface equipment, including a 20-stamp mill, two years ago, since which time the property has been idle. The mine was active and profitable 20 years ago, the workings having attained a depth of 700 ft. The workings are to be unwatered, the shaft is to be sunk deeper, and a mill may be built.

A number of hydraulic miners of this county have been enjoined against operating their mines, after inspection by agents of the Anti-Débris Association. Restraining dams and settling reservoirs, which were built at You Bet in accordance with the provisions of law and under permit of the Anti-Débris Association, after two years trial have failed to satisfy the farmers and fruit growers in that vicinity, who allege damage to growing vegetation as the result of hydraulic mining.

(Special Correspondence.)—The Delhi Mining Co., of San Juan district, expects to shut down its 20-stamp mill and mine for a year, during which time a flume and ditch will be built for power purposes to supply the mine and mill. The Delhi mine is on the south fork of the Yuba river, H. Eddie being superintendent.

Grass Valley, June 8.

Placer County

(Special Correspondence.)—The Orpheum mine has a new shoot of ore on the 300-ft. level. The operation of the new 10-stamp mill results in saving about $8 per ton on the plates. C. Peach is superintendent.

Auburn, June 10.

Plumas County

Hewitt Brothers are reported as intending to build a 5-stamp mill at their mine on Hopkins creek. It is claimed they have a big body of ore which has been opened by an adit.

Shasta County

The Balaklala Con. Copper Co. has been cited to appear in the United States Circuit Court, at San Francisco, June 19, to answer the charge of the Shasta county farmers of violating the court's decree of July 8, 1910, relative to the elimination of noxious fumes from the smoke emitted from its copper furnaces. The complainants allege non-elimination of free sulphuric acid from the smoke; that by the Cottrell process all the solid particles are not removed from the smoke; that more than 0.75% of sulphur dioxide by volume is permitted to pass into the atmosphere, and that such sulphur dioxide is injuring vegetation.

Sierra County

The Irelan mine, near Alleghany, is being operated by Fred Clark, who has the property bonded. The work is in charge of George Hegarty, who recently opened a shoot of ore through which free gold is disseminated; there is also some arseno-pyrite containing gold. The shoot was opened by a cross-cut at 200 ft. below the surface. A raise is being driven on the ore so that stopes may be opened. The Independence G. M. Co., operating at Alleghany, is erecting a 5-stamp mill. A carload of machinery for a mill to be built at the San Luis mine, near Sierra City, is to be hauled to the property the last of this month. Homer Gould and Ed Poggi have a bond on the Rosasco & Danero quartz mine, 3 miles west of Downieville. They expect to extend the adit that was driven by a former operator.

Trinity County

The La Grange hydraulic mine, near Weaverville, has a 3000-ft. sluiceway, riffled with 6-ft. steel rails, 300 tons of which were recently shipped to Redding and hauled to the mine to replace worn-out riffles. Last year 150 tons of similar rails were required for this purpose.

Tuolumne County

The Black Oak mine, situated in the vicinity of Soulsbyville, is being operated by the Black Oak Development Co., which took possession of the property in January 1909, under a lease and bond. This company is composed of Charles E. Knox, president of the Montana-Tonopah M. Co., John Bryant of Kansas City, and S. A. Knapp of San Francisco. The Black Oak, which is on the east belt, in a grano-diorite country, was operated during a number of years by former owners, who sank a 1300-ft. incline to conform to the dip of the vein, which is about 70°, and from this incline 15 levels were driven on the vein. It is claimed the value of the ore mined under the old regime was close to $2,000,000. In driving north of the shaft the former operators ascertained that the orebody was cut off by a fault, beyond which the ground was much broken, with no defined vein. When the company now in control took charge, the workings were unwatered, the shaft was sunk 120 ft. deeper, and the sixteenth level was established. It was found that the disturbed condition was within 100 ft. of the shaft on the north, at the sixteenth level; and by cross-cutting 98 ft. west on the fifteenth level the vein was opened on the opposite side of the fault, where it proved to be 5 ft. in width, the ore therein assaying about $40 per ton. Drifts are being driven on the vein in opposite directions on the fifteenth level. This part of the vein, beyond the fault, is to be opened by cross-cuts on all levels from the sixteenth to the seventh, a distance of about 1000 ft. on the dip. The surface indications are such as to lead to the opinion that this orebody extends to the surface. Shipments of the higher-grade ore, amounting to 100 tons per week, are being made to smelters, while the 40-stamp mill is being operated on that of lower grade. Important changes will be made in the mill, to provide for fine crushing and cyanidation. Roger C. Knox is superintendent.

COLORADO

Gilpin County

The London group of claims in Twelve Mile district, near Apex, is under lease and bond to A. Bergeron, George Potvin, and A. T. Holman, all of whom are Cripple Creek operators. The property has some development, by which a 6-ft. vein of ore assaying $12 per ton has been opened.

Routt County

The Royal Flush mine, situated at Hahn's peak, thirty miles north of Steamboat Springs, has been opened by means of a 2000-ft. cross-cut, whereby a number of veins containing milling ore have been interseeted. Some drifts in ore have been driven on several veins, one of the latter being 9 ft. wide. The ore contains gold, silver, and copper. The property is controlled by H. O. Granberg and associates, who are erecting at the mine a 100-ton concentrator.

San Juan County

The Iowa-Tiger Leasing Co. is mining and concentrating 2500 tons of ore per month, the product of which is 400 tons of concentrate worth $40 per ton net. This company is operating the Iowa and Royal Tiger mines in Silver Lake basin, at an altitude of about 12,000 ft. The 1½-mile tramway leads to the mill, which is 2000 ft. lower.

The Gold King mine and mill, on Cement creek, near Silverton, are now being operated under the management of J. O. Campbell. The mill is crushing 250 tons per day with 80 stamps, producing 55 tons of concentrate. The Hercules mine, near Silverton, has been sampled and may be operated again under direction of Thomas Kane.

San Miguel County

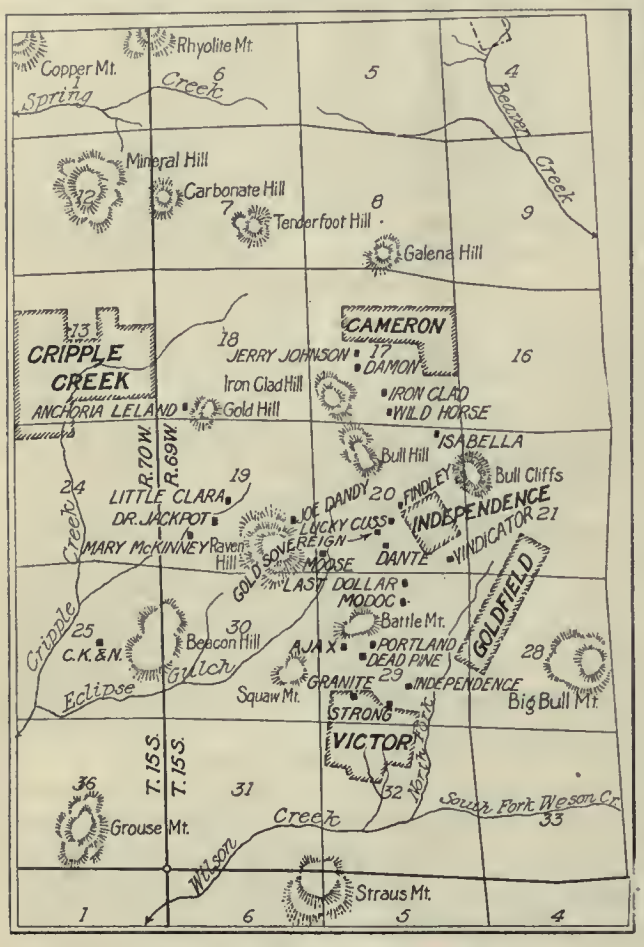
The Telluride *Journal* announces that the Ballard mine, situated in the centre of the San Juan country, is to be reopened by J. C. Weller and associates. The Ballard was productive in earlier days. The San Bernardino mine, near Trout lake, is being further developed under the superintendence of H. Olson. The property was examined recently by E. E. Rowe. There is said to be a considerable amount of ore in sight.

Teller County (Cripple Creek)

The Spur-Daisy G. M. Co., operating as lessee on the Oro lode of the Colorado Springs G. M. Co., Ironclad hill, discovered a vein at the 100-ft. level, the ore in which assayed $25 to $30 per ton. A steam plant has been put in position, and arrangements are being made to operate air-drills. A shipment of the ore is to be made. J. F. Reynolds and T. F. Buckley, having a lease and option on part of the Bogart

claim between Raven and Bull hills, made a shipment of ore that sampled about $25 per ton. Hills & Co., operating the Amanda mine under lease, situated at Windy point, have shipped 9 cars of ore from the Flag Staff shaft. The ore samples about $20 per ton. G. C. Blakey has shipped a car of ore from the Katie Hollis mine, which adjoins the Amanda.

The American Eagle mine, Bull hill, located by W. S. Stratton in 1890, is under lease to the Colorado Mines Investment Co., and under this lease there are 12 sub-lessees, 8 of whom are shipping ore. One of the latter is Mathison & Co., who have mined and sacked ore on the Porcupine vein, at the 100-ft. level, 500 lb. of which brought $2104 per pound. This is as high-grade ore as has been found in the history of the district. J. A. Jones, another sub-lessee, mined and sold 25 tons of ore at $72.40 per ton. The South Burns M. Co., working as lessee at the Burns shaft of the Acacia G. M. Co., last week shipped 50 tons of ore which



MAP OF CRIPPLE CREEK DISTRICT.

sampled $31.60 per ton. Operators under the Cookerly lease on the Prince Albert claim, Beacon hill, sold 30 tons of ore, the gross returns of which were $43.60 per ton. The ore was taken from the shoot developed by lessees, and lies south of the old shaft. The Modoc M. & M. Co. hoisted and shipped 5 cars of ore from the 950-ft. level of its Ocean Wave mine during May, which yielded $60 to $100 per ton. Lessees, working on the higher levels of the same mine, produced 175 tons of ore during May that brought $30 to $50 per ton. Melville Rapp, lessee at the Dante No. 2 shaft, mined and marketed 350 tons of ore in the month of May which sampled $20 to $30 per ton. The Dante company is sinking its No. 1 shaft. The Midget and Bonanza Queen claims, Gold hill, are being subdivided for convenience in letting leases. The Lucky Corner M. & L. Co., operating on ground owned by the Doctor-Jack Pot M. Co., between Raven and Gold hills, made a 2-car shipment of ore running $40 per ton. The ore was taken from the vertical vein of the Lucky Corner mine. Two cars of ore were recently marketed by William McGee and associates, who are operating under lease the Half Moon mine, on Gold hill. The mine belongs to the Matoa Gold M. Co. The main shaft of the Vindicator mine is being sunk below the 1500-ft. station. The Hull City shaft of the Vindicator company also is to be sunk deeper. Ore of good grade is being hoisted from the 1300-ft. level of the main shaft. The Union Leasing Co., operating at the Vindicator's Husted shaft, has opened a 7-ft. body of ore that assays $30 per ton, and about 30 cars of ore per month are being hoisted from the fourth and fifth levels. The shipments from the El Paso mine, Beacon hill, are averaging about 4 carloads per day.

IDAHO

Boise County

(Special Correspondence.)—The White Quartz Mining Co., operating the Woodburn placers, and the Mann & Hanson ground, employs 35 men. Four Hendy giants are in active use, and during the season, which is expected to end July 10, it is estimated that 600,000 cu. yd. will be sluiced. The values for this year are not definitely known, but last season on the same hill the ground averaged 22c. per cubic yard. On the one hill, where present operations are concentrated, the available ground is estimated at 40,000,000 cu. yd. C. F. Herrick is manager.

Idaho City, June 7.

Idaho County

The Last Chance group of five claims is situated within two miles of Elk City, and is owned by James Larsen of that place and Wilson Brothers of Spokane. It has two veins, one of which has been opened by a 370-ft. adit, and the other by a 200-ft. adit. The former vein has a width of 5 ft., within which is a 2-ft. pay-streak assaying about $200 per ton in gold. The latter vein is about 6 ft. wide, and contains a pay-streak of ore assaying about $15 per ton in gold. The two veins are 125 ft. apart.

Lemhi County

The Commodore M. Co., developing the Commodore mine, situated within three miles of the Gilmore & Pittsburg railroad, has a narrow vein of ore said to sample 300 to 1500 oz. silver per ton, and 12% lead. A shipment of the ore will be made to a Salt Lake smelter. The silver is argentite. New hoisting equipment is to be provided.

Shoshone County

(Special Correspondence.)—The interest of Charles H. Reeves in the Hercules mine, amounting to $^{16}/_{256}$ of the whole, was sold recently to Eleanor Day Boyce for $312,500, which is on the basis of $5,000,000 for the property. The ownership in the mine now stands as follows: The Day family, headed by Harry L. Day, $^{116}/_{256}$; August Paulsen, Spokane, $^{66}/_{256}$; the Markwell family, Los Angeles, $^{25}/_{256}$; L. W. Hutton, Spokane, $^{25}/_{256}$; Daniel Cardoner, Spain, $^{16}/_{256}$; F. M. Rothrock, Spokane, $^{8}/_{256}$. Dividends paid during the last 9 years have aggregated about $4,000,000; the amount paid in dividends for the year ended May 1, 1911, was $418,542. For that year there was mined 25,765 tons of ore, the gross value of metals recovered therefrom being $1,249,081. The costs of mining were $142,420; transportation, $178,503; reduction and sale, $195,622; improvements, including the mill at Wallace, $313,992; total, $634,915. There is being concentrated at the new mill about 400 tons of ore per day, and shipments of high-grade ore direct to the smelters amount to about 500 tons per month. The ore-shoot, where it was tapped by the No. 4 adit, has been proved a distance of 300 feet.

Wallace, June 10.

MICHIGAN

Houghton County

The May output of the Mohawk Mining Co. was 589 tons of copper, making 2914 tons for the first five months of this year. The Globe Mining Co. has been incorporated to take over and develop the Globe tract, adjoining the Champion on the south. The incorporators are J. E. Gay, J. R. Stanton, R. D. Rickard, and W. H. Leggett, who own all the stock of the company. The Old Colony company has decided to commence operations. Its group lies directly north of the St. Louis group, and the favorable result of

the work on the amygdaloid lode of the latter was what decided the Old Colony company to renew development.

MONTANA

Jefferson County

(Special Correspondence.)—Julius Barnes and associates, of Duluth, have obtained a lease and bond on the C. & D. mine at Elkhorn, and have incorporated the Elkhorn & Duluth Development Co., by which the mine is to be operated. The property has been developed by means of inclined shafts. The ore contains gold and lead, a large tonnage of which is said to have been opened. It is thought the lead can be taken out by concentration, and the tailing cyanided to extract the gold. The building of a milling plant will not be decided upon until after more development has been done.

Elkhorn, June 7.

Lincoln County

(Special Correspondence.)—The Snowshoe mine, which was purchased within the last six months by the Pacific Coast Smelting-Refining-Mining Co., is situated in the Cabinet range, 20 miles south of Libby, and is at an altitude of 4600 ft. above sea-level. The property has a vertical vein, 15 to 20 ft. wide, between well defined walls. The ore, as an average, samples $2.50 gold and 7 oz. silver per ton, and 8% lead. The mine is worked through a 3-compartment shaft and several adits, the greatest depth being 900 ft. The ore-shoot has been explored for a length of 1100 ft. It is stated that there are 80,000 tons of ore blocked out in the mine. The concentrating mill, of 300 tons daily capacity, which is in operation, was built by former owners about 1904. It is equipped for operating either by water or steam power. The mine workings, the mill, and premises are lighted by electricity. A force of 80 men is engaged at the mine and mill. The ore is concentrated about 8 tons into 1, and the grade of the concentrate shows an extraction of 75 to 80%. The shaft is being sunk to greater depth, and further development is in progress. The Snowshoe was closed down by reason of litigation from 1906 to the date of the purchase by the company now in control. E. H. Wilson, consulting engineer, who is directing operations, states that the railroad of the Libby Lumber Co., which is now within 7 miles of the mine, is to be extended to a place 5 miles closer this season.

Libby, June 9.

NEVADA

Esmeralda County

(Special Correspondence.)—The Atlanta will have a 1500-ft. shaft, to be sunk by the Queen Con. M. Co., which

FLORENCE MILL.

owns ground in the district, and has a lease on the Atlanta, on which it has resumed work. The lessee has been driving to the southeast on the 705-ft. level to explore the ground between the shaft and the boundary line of the Florence. The company has decided to sink to a depth of 1500 ft., and this work will begin within a short time. The Precious Metals Co., another lessee on the Atlanta, is exploring on the 730-ft. level and is now believed to be close to the northern extremity of the great andesite dike which, beginning at the south of the Florence hill, apparently forms the centre of fault displacement, throwing the entire formation far to the east, and beyond which it is hoped to pick up the southern extension of the Florence ore channel, cut off by this dike.

The Florence Goldfield mine has a number of improvements in the surface plant. The April report of Willis Lawrence, superintendent, shows that during that month the company's mill treated 5100 dry tons of ore, an average of 167 tons daily. The extraction was 94%, and costs of operation are given as follows: Mining, $1.10; development, $1.24; milling, $2.47; total, $4.83 per ton. Bullion tax, and incidental expenses, amounting to 12c., bring the total operating costs to about $4.95 per ton, the lowest figure achieved in this district. Some new equipment has been added to the machine-shop, a new electrical shop is being equipped, and a change-room will be built for the use of the miners. The company employs an average of 110 men, 75 of whom are engaged underground, 20 in the mill, and 15 at other work.

In the northern part of Goldfield district, the Goldfield Belmont Co. has exposed ore of good grade in the main drift on the 300-ft. level. This property is controlled by the men who dominate the Tonopah Belmont Development Co., and the work is being carried on under the supervision of that company's manager. Several shipments of ore running $100 per ton were made from the Belmont by lessees last year, the ore having been taken from the 50 and 150-ft. levels. Ore taken from a winze sunk on the 150-ft. level assayed as high as $1400 per ton gold. The 300-ft. drift has been driven for the purpose of getting under this orebody. This is the most northerly point in the Goldfield district at which pay-ore has been found.

Lessees have been shipping ore in small quantity from the Diamondfield Black Butte and Daisy; development on the latter will be extended into the Great Bend, adjoining, where ore was exposed by lessees on the 400-ft. level. The Marquette lessees are devloping on the east side of Vindicator mountain, on the Talmage group. The Sandstorm-Kendall Con. Co. is driving and cross-cutting from the old Kendall shaft and has some good ore, while lessees on the Sandstorm have mined ore of shipping grade. The Florence American Co., working on the Rustler Fraction, adjoining the Florence Goldfield on the southwest, has sunk the shaft to a depth of over 700 ft., and is exploring on the 700-ft. level to find the extension of the Rogers-Syndicate ore-shoot.

Engineers have been examining and sampling the ore of a group of 16 claims, known as the Rea property, situated 20 miles south of Goldfield, at the foot of Jackson mountain. A mill-run has been made of the ore from this group at the Pigeon Springs mill, near Lida. It is understood the property has an excellent showing of high-grade copper ore, accompanied by gold and silver. The 90-ft. shaft was sunk in ore, and the dump material is high grade. An adjoining group of 12 claims recently was examined by representatives of Eastern investors who are considering its development. The latter group is owned by Richard Donnelly and has a surface showing identical with that of the Rea group. The survey of the projected railroad between Cuprite and Lida passes within two miles of these properties and the Lida pipe-line and electric-power line are within a short distance.

Goldfield, June 10.

Humboldt County

Donald Ferguson, of Goldfield, acquired the Ohio mine, on Rebel creek, for Eastern people last year. He has a force of men engaged in prospecting and development. The tonnage of ore of milling grade now exposed is said to be sufficient to warrant the building of a 20-stamp mill, construction work on which may begin in a few weeks. The ore is said to average $17 per ton.

Lyon County

Various small mines at Silver City, including the Midas,

Carson, Underground, Overland, Hayward, Hartford, St. Louis, Justice, Cook & Gray, Buckeye, Kossuth, and Silver Bill, are producing 1000 to 1500 tons of ore per month, all of which is being treated at local mills. The McTigue 15-stamp mill and the Phillips mill work mostly on ore from lessees; the Phillips, Donovan, and Woodbury cyanide plants are running on tailing.

Nye County

The Mercury Mining Co., in which Mark L. Requa and J. H. Mackenzie are interested, has a cinnabar mine situated 80 miles from Tonopah, at which a retorting furnace and other equipment are being provided at an expense of $10,000.

Storey County (Virginia City)

The Mexican G. & S. M. Co. has a force of 43 miners at work. The report of Whitman Symmes, superintendent, for the week ended June 10, shows that three carloads of ore were shipped to the smelters, and that the gross output for the week was valued at $25,100. Mining operations on the 2300-ft. level resulted in extracting 51 mine-cars of ore of an assay-value of $54.48 per ton. There were 39 cars of ore taken from the north drift No. 3, off west cross-cut No. 2, on the 2400-ft. level, which assayed $9.20 per ton; also 21 cars of ore averaging $12.21 per ton, 24 cars running $7.16 per ton, 66 cars at $45.32, and 3 cars assaying $33.90. Extraction of ore at various points on the 2500-ft. level consisted of 76 cars averaging $86.53, 3 cars at $52.20, and 133 cars assaying $87.79 per ton.

OREGON

Baker County

E. P. Spaulding, J. C. Haas, W. H. Turner, and others of Spokane, have taken a bond on the Humboldt and Gorman mines, situated in Mormon basin. The Humboldt is one mile west of the Rainbow, and on the same lode. It has been developed by a 200-ft., 2-compartment shaft, and is equipped with a 10-stamp mill. It was formerly operated by J. A. Howard, Fred R. Mellis, John Arthur, and others of Baker.

UTAH

The International Smelting & Refining Co. now has four reverberatory furnaces in operation at its Tooele plant, and

MAP OF UTAH.

it is understood that the fifth furnace will be constructed this year, which will give the plant a capacity of 1500 tons of charge per day, consisting of calcined copper ore and copper concentrate, together with the fuel required. Blast-furnaces for lead smelting are being built, the foundations for which are being laid. In the meantime lead ores are being purchased and stored in the ore-bins.

The new inclined 3 compartment main winze of the Utah Consolidated, at its Highland Boy mine, Bingham district, has reached a depth of 1000 ft. It starts on the No. 7 haulage level, and is designed to be the means of developing the orebody at greater depth. The shipment of ore from this mine over the aerial tramway to the International smelter amounts to 500 to 600 tons per day. The Utah Copper Co. produced 8,169,248 lb. of copper in April, which is nearly a million pounds more than the March output. The production of the Chief Consolidated mine, at Eureka, from September 1909, to April 30, 1911, was 10,320 tons of ore, the net returns for which amounted to $249,131, an average of $24.19 per ton. The workings extend to a depth of 1675 ft., but most of the present work is on the 1400-ft. level. L. E. Riter, superintendent of the Dragon mine, near Mammoth, is driving a drift at the 800-ft. level on the Iron Blossom fissure, in which there is some galena in quartz. This drift is to be continued northward on the fissure to find an ore-shoot. Driving from the 1000-ft. station toward this fissure is in progress. The Eagle & Blue Bell mine at Eureka, controlled by the Bingham Mines Co., has first-grade ore in the bottom of the shaft, 68 ft. below the 1200-ft. station. Driving in ore at this point is in progress. The shaft of the Yankee Con. M. Co., at the north end of the Tintic range, and in the vicinity of Eureka, has reached a depth of 1820 ft., the intention being to sink to water-level before doing lateral development. B. N. Lehman of Salt Lake City is manager for this company.

The ore shipments for May from the mines of Park City, as reported by the Park *Record*, aggregated 236 carloads, or 9823 tons, distributed as follows: Daly West, 2639 tons; Daly-Judge, 1783; Silver King Coalition, 3349; New York Bonanza, 100; Ontario lessees, 153; Frank Daily, 41; Grasselli company, 480; Hanson company, 44; C. Anderson, 30; E. J. Beggs, 28; zinc ore shipped by Daly West, 532 tons.

CANADA

British Columbia

It is announced that the Granby mines, at Phoenix, and the Granby smelter, at Grand Forks, have begun operating, the latter with six furnaces. Their closing down was due to the inability of the Granby company to obtain its regular supply of coke from Crows Nest, where the coal mines and coke ovens were shut down on account of a labor strike. It is stated that the company is now getting its coke from Pennsylvania.

Yukon Territory

All the dredges in the Dawson district have been in operation since May 1, and several new dredges are being built. Operators of hydraulic plants began work in May, and those who got out winter dumps have been sluicing them. The Consolidated Forty-Mile company has commenced its season's work on Forty-Mile creek: and the Milvain company is operating a dredge in that locality, and may build a new dredge this summer. George J. Milton of Minneapolis has a force of men at work on the Tantalus coal mines, at Five Fingers, on the Yukon. The Coal creek coal mines, situated 35 miles north of Dawson, are being operated, the output being sufficient to supply much of the local demand. Coal produced at the Tantalus mines is used on the steamboats which ply on the Yukon between Whitehorse and Dawson.

MEXICO

Chihuahua

(Special Correspondence.)—The Republica Mining Co., operating a mine and mill at Sanz, some distance from Ocampo, during April crushed 1137 tons of ore, from which silver and gold were extracted, valued at ₱76,975. The operating costs were ₱43,549; construction expenses, ₱6680. This company, while operating far away from the railroads, has managed to work continuously during the period of insurrection.

Ocampo, May 20.

Book Reviews

Any of the books noticed in these columns are for sale by, or can be procured from, the MINING AND SCIENTIFIC PRESS.

DICTIONARY OF ENGLISH AND SPANISH TECHNICAL AND COMMERCIAL TERMS. By William Jackson. Pp. 164. Pocket size. Spon & Chamberlain, New York, 1911. For sale by the *Mining and Scientific Press*. Price, $1.

This little book is designed to answer the needs especially of those engaged in the iron, steel, hardware, and engineering trades. It is particularly valuable in that it includes not only the words for the articles dealt in, but those necessary in ordinary commercial transactions.

THE IRON ORES OF LAKE SUPERIOR. By Crowell and Murray. 186 pp., ill., maps, and charts. Penton Pub Co., Cleveland, 1911. For sale by the *Mining and Scientific Press*. Price, $3.50.

This is an exceedingly useful compilation of scattered information which has already appeared in other forms, and contains brief descriptions of the geology, mining methods, and transportation of these ores, their classification, sampling, analysis, and methods of computing prices from analyses. The most important feature of the book is the gathering in a handy volume of the chief facts concerning each of the more important mines of the Lake Superior district, including those of Canada. A more complete index would add to the very great usefulness of this reference handbook.

WEST AUSTRALIAN MINING PRACTICE. By E. D. Cleland. Pp. 268. Ill. Chamber of Mines, Kalgoorlie, 1911. For sale by the *Mining and Scientific Press*. Price, $8.

This volume, prepared under the auspices of the Chamber of Mines of Western Australia and published by that body, is a comprehensive summary of Western Australian mining practice. The book is based upon a series of articles written by Mr. Cleland for the *Journal* of the Chamber, and published during 1907 and 1908; these have been recast and expanded by a committee of representative engineers, so that no better review of present practice could well be obtained. In the eighteen chapters, all the phases of mining practice are discussed, and illustrated by numerous charts and diagrams. As a reference book of Australian practice, especially for Kalgoorlie, it is unexcelled, and with its companion volume by Gerard Williams upon the metallurgical practice of Western Australia, which is expected to appear in the near future, is likely to be of great value and interest to American engineers.

METALLURGY. By W. Borchers. Authorized translation from the German by William T. Hall and Carle R. Hayward. John Wiley & Sons, New York, and Chapman & Hall, Ltd., London, 1911. For sale by the *Mining and Scientific Press*. Price $3.

This little volume, evidently intended by the author as the syllabus of a course of lectures, should be used with caution by others than students. When it is noted that 23 pages are devoted to the metallurgy of gold and 11 pages to antimony, one feature of the work need not be commented on at greater length. In addition to this lack of balance, the volume is distinctly European in its viewpoint, and in several instances, gold and copper for example, the text needs copious commentary by the instructor to bring it more closely in line with American practice. A good feature of the book is its presentation in brief form of the results of advanced metallurgical study of the last decade; material that could otherwise be gathered only with much labor from the pages of technical journals, most of them French or German. For general brief reference it is likely to prove more convenient than Schnabel's two-volume treatise, and for this reason it will be welcomed as a supplement to texts on the metallurgy of iron, gold, copper, lead, silver, and zinc. Its treatment of the minor metals is much the best of any text now available.

Decisions Relating to Mining

Specially reported for the MINING AND SCIENTIFIC PRESS.

BREACH OF MINING CONTRACT

A person who was in default in the performance of the obligation of a contract to develop a mine was not in a position to sue the other party to the contract for an accounting. And where such developing contract provided that the forfeiture of the stock of the person undertaking to make a dividend-producing mine out of the premises, was the only relief to which the other party was entitled, on failure of the obligor to make the premises a dividend-producing mine, the forfeiture of the stock constituted the entire measure of damages in favor of the other parties to the agreement.

Catterlin *v.* Voney, 177 Federal, 527. March 1910.

FRAUD OF AGENT IN PURCHASE OF MINE.

An agent for another to secure options on mining property and to purchase mines for another is bound to deal fairly with his principal; and where such an agent represented to his principal that a certain mine could not be bought for less than a stipulated sum, when in fact the agent had an agreement with the owner of the mine that he was to receive a certain commission if he sold the mine to his principal for the price represented, which fact he concealed from the principal, was held to be a fraud on the principal, and the amount of the commission received by the agent upon the sale of the property could be recovered by the principal.

Shubart *v.* Federated Mines & Milling Co., (Missouri) 128 Southwestern, 2. May 1910.

LIABILITY OF MINE OWNER FOR DAMAGES TO MINER CAUSED BY THE NEGLIGENCE OF ANOTHER MINER.

The statute of Montana makes a mine operator liable for damages to a miner injured through the negligence of another miner. It also provides that in case of death of the miner from any injury so sustained the right of action shall survive to and may be prosecuted by his heirs. Under this statute in an action by the heirs for the death of a miner caused by the negligence of another miner, the scope of the recovery is the same as his would have been but for his death, including damages for the pain and suffering he endured and for his diminished and lost earning capacity for the period of his natural expectancy. And where such an action was based only on negligence of the engineer in handling the cage, evidence was admissible to show that the cage was without doors, as bearing on the degree of care that the engineer with knowledge of such facts was required to exercise in handling the cage.

Beeler *v.* Butte & London Development Co., (Mont.) 110 Pac., 528. July 1910.

USE OF LAND—INJURY TO ADJOINING LAND.

A landowner is not liable for incidental injuries to an adjoining landowner in the reasonable use of his property. But the use of land by one landowner for profit in such a manner as to practically confiscate or destroy adjacent property is not a reasonable use where such injury can be prevented at an inconsiderable cost. Under this principle of law the owner of land occupied and used for mining purposes, while the adjoining lands were servient to the ordinary surface flowage, and to such surface flowage that was contaminated by deleterious matter by which a reasonable use of such land might impregnate the flowage. Yet such adjacent land was not servient to an unreasonable artificial flowage caused by pumping water largely impregnated with salt and poisonous mineral substances from oil wells on the dominant land, either flowing upon such servient land or collected into artificial channels and cast upon it.

Niagara Oil Co. *v.* Jackson, (Ind.) 91 Northeastern, 825. May 1910.

Personal

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

W. L. Saunders is at Denver.

Bertram Hunt has gone to New York.

M. S. MacCarthy is in San Francisco.

W. J. Sharwood is visiting California.

W. W. Mein has been in San Francisco.

C. S. Thomas, Jr., has been at Goldfield.

Carl Hoffman is visiting San Francisco.

Gelasio Caetani has been at Telluride, Colorado.

W. H. Aldridge will he at Los Angeles next week.

Hennen Jennings is in San Francisco this week.

W. A. Knol, of Rotterdam, Holland, has left Denver for New York.

E. M. Rabb is at Denver, after a six weeks' tour of the West and Southwest.

G. I. Adams has returned to Washington, D. C., after some years residence in the Orient.

M. W. Summerhayes has been appointed manager of the Swastika mine at Swastika, Ontario.

R. C. Kline has heen appointed metallurgist for the Farmers Mining Co. at Eureka, Nevada.

Duncan MacVichie, of Salt Lake City, was at the Nevada Douglas mine, near Mason, Nevada, last week.

A. C. Lawson is in Canada, where for six months he will be engaged in work for the Canadian Geological Survey.

C. F. Dike, Jr., of Cripple Creek, has been appointed manager for the Crown Chartered Co., Porcupine, Ontario.

R. B. Lamb has completed a professional trip to Porcupine and South Lorrain, and is now at Swastika, Ontario.

H. P. Henderson, of the firm Mines Management Co., New York, is making an examination at Porcupine, Ontario.

W. D. B. Motter, Jr., has been appointed manager for the Canada Iron Mines, Ltd., with headquarters at Trenton, Ontario.

Marshall D. Draper has gone to Alaska as engineer for the Hubbard-Elliott Copper Co., operating in the Copper River country.

R. W. Raymond and R. H. Richards have been elected to honorary membership in the American Institute of Mining Engineers.

J. S. Austin, president, and W. W. Charles, comptroller, of the Tonopah Mining Co. and other properties, were in San Francisco.

V. F. Marsters, consulting geologist, of Lima, Peru, has returned to New York on professional business. Until August 1 his address will be Substation 84, New York City.

Edwin A. Sperry has accepted the professorship of metallurgy at the Imperial Pei-Yang University, Tientsin, and will sail on June 28. R. Van A. Mills is now professor of mining in this University. N. F. Drake has accepted the associate professorship of economic geology in Leland Stanford, Jr., University.

L. Vogelstein & Co. give the following figures of German consumption of foreign copper for the months of January to April 1911:

	Tons.
Imports of copper	57,849
Exports	2,654
Consumption	55,195

as compared with consumption during the same period in 1910 of 54,663 tons. Of the above quantity 50,261 tons was imported from the United States.

On Monday, June 5, 1911, the Bunker Hill & Sullivan M. & C. Co. paid dividend No. 165, of $65,400. This makes the total amount of dividends paid $12,767,250.

EDITORIAL

LONG LIVE GEORGE V, King of England and Emperor of India. British subjects throughout the world joined on Thursday last in celebrating the accession of their sovereign. The pageants, naval and military reviews, balls and social gaieties, by which the occasion was marked, have filled the columns of the daily press and the magazines, and the whole world has read of them with interest, an interest that is also rooted in the same idealism that makes Englishmen, traditional lovers of liberty, celebrate the placing of a king above them. The ideal king is the superman, and in paying him homage his subjects magnify the best that is within themselves. The American people joined in spirit with their British cousins in celebrating the day.

TUNNEL-DRIVING has always attracted much attention in Colorado, and at the Laramie-Poudre tunnel exceptional progress has been made. In May the advance was 635 feet. Up to May 25 the work was driven at a rate which would have given 700 feet for the month, but broken ground being penetrated the average was lower, though still highly creditable.

ABRAHAM GONZALES, governor of Chihuahua, has declared that under the new régimé in Mexico every effort will be made to restrict the operations of 'foreign monopolies' now existing in Chihuahua. Second thoughts are the best, and it is not too much to hope that in the end it will be recognized that the interests of Mexico, as well as of outside nations, are best served by fairness and justice to all.

CLOSING of the smelting plant of the First National Copper Co. at Coram is the most recent chapter of the smelter fume controversy in California. The experimental work done on behalf of the farmers showed that the smelter was not complying with the terms of the injunction granted last year and the company therefore agreed to close down the plant as soon as the ore now on hand is smelted. Plans for the future have not yet been made.

NO MAN is ever hurt by assistance given to others, and the plea which Mr. C. A. Chase makes in his valuable description of practice at the Liberty Bell mill should meet with a generous response. Mining is not a competitive industry, in most cases, and in any event, the benefit which each engineer has received from his fellows lays upon him an obligation to give in return, whenever he can do so without injury to himself or those to whom he is responsible. It is to be regretted that instead of growing, the exhibition of this spirit has seemed recently to decrease.

REDUCTION of the duties upon wool, raw and manufactured, is a signal victory for the advocates of a lower tariff. The consumers of wool, the whole people, will benefit by the change, and it remains to be seen whether the manufacturers will be much injured. One lesson is plain; difficulties may arise when changes are made in the conditions governing an industry. A machine that gives satisfactory service will perhaps run better when some of

its parts are taken out and replaced by lighter ones; but while these are being fitted in place the machine is out of commission. Fix the machine, it needs it; but do not tinker with it, for little good is likely to result from so doing.

CEMENT has entered so largely into construction work of recent years that the domestic production was, until recently, unable to supply the demand. From 1890 to 1900 imports amounted to three or four million dollars worth per year, chiefly from Germany. In 1905 imports and exports nearly balanced and in 1910 the excess of exports over imports was over $3,000,000. Of our exports, nearly all go to Central and South American countries, nearly a million barrels going to Panama last year.

EXTENSION of the deep-drainage adit at Cripple Creek is proposed, and a fund of $50,000 is being raised for that purpose. While the water has not been lowered as rapidly as was anticipated, substantial benefit has already accrued. About fifty feet of water remains in the lowest level of the Portland mine, but it is expected that this will disappear in a few months. Contrary to expectations, mines in the western part of the district are not being drained notably faster than are those farther east.

EMERGENCY shafts, essentially large drill-holes, were discussed by Mr. Edward Rowe in a recent number of the *Scientific American*. No doubt they could often be used to advantage, but the larger use for such drill-holes would seem to be to supply air, food, and information to imprisoned men. At Ely, Nevada, among other points, drill-holes and pipe-lines already have been so used, and rescue chambers connected with the surface by pipe-lines will doubtless in time become regular parts of the equipment of coal mines.

Errors in Mine Sampling

The old story of the accountant who requested a manufacturer of instruments to make for him a glass ruler with a perfectly straight edge is often cited as an instance of the high cost of obtaining great accuracy and the impossibility of its perfect attainment. On another page Mr. Morton Webber calls attention to the errors in the sampling of a mine which seem impossible of avoidance, and draws attention to the curious fact that the error is nearly always in favor of the mine. Numerous cases of this will occur to every engineer. In a certain gold mine, for example, where the quartz vein ranged from 2 to 40 feet in thickness, two capable and careful engineers, in independent examinations, determined the average width of the vein as 9¼ and 9 feet, respectively, with an average content of $8.67 and $8.64 per ton. So close an agreement as this might reasonably be taken to indicate the accuracy of the work, yet two subsequent mill-tests showed $8.10 and $8.20 per ton, or approximately 6 per cent lower than the estimate. In the case of a well known copper mine even a mill-test proved unreliable. A series of mill-tests, made on a large scale, showed the content of the ore to be high enough for profitable working, yet actual work later proved that this was not the case. Probably the unconscious selection of the miners in breaking ore in the stopes introduced the error. In the training of young engineers, research work is often introduced in order to teach the student how subject to error even the most careful work may be, and the necessity for constant attention to this important phase of experimental work. Some years ago R. S. Woodward delivered an address on 'Observation and Experiment' that, though written by a pure scientist, should be read by every engineer who has occasion to make experiments and tests in the course of his professional work.

Mining and Metallurgical Society Problems

When the Mining and Metallurgical Society of America was organized, its sponsors had in mind three departures from the established practice of the older and larger society, the American Institute of Mining Engineers: First, it was thought desirable to bring together, if practicable, a body of the more active and influential members of the profession, and, to that end, to establish somewhat more rigorous qualifications for membership than those of the Institute. Second, it was desired to promote acquaintance and coöperation among the members by more frequent meetings, and with that in view, local sections were established. Third, with this smaller and more closely knit membership, it was believed that it would be both possible and desirable to secure formulation and expression of opinion among engineers regarding matters of public moment concerning the profession as a whole. The attempt was first made to secure such changes in the organization and practice of the Institute as would permit it to serve these functions, but, it being held by the officers of the Institute that this was neither desirable nor feasible, a new society was organized. It has now been in existence three years, and the time is opportune to measure results and raise the question whether continued separate existence is to the best interest of the profession.

As to the first purpose of the new society, allowing frankly for serious mistakes of inclusion and exclusion, a fair measure of success must be conceded. Not all the leaders of the profession have been interested, and by no means all or a majority even of those who are qualified for membership by position and attainments have joined the movement. At the same time the list of members is one which commands respect, and the membership is growing at a comfortable if not a rapid rate. As acquaintance among the members improves, and the scope and purpose of the society becomes better known, it is but fair to anticipate that more of the desirable men will become members. As has been the history of most new societies, an over-exclusiveness prevailed at first, and an unnecessary and regrettable affront was put on several excellent engineers whose applications were rejected; probably because of lack of wide personal acquaintance. Changes in the rules have made this impossible, and past mistakes have been rectified in part. The financial affairs of the Society are in excellent shape. In these particulars, at least, a creditable measure of success must be conceded.

As a means of promoting acquaintance and coöperation among members, the Society has also served a most useful purpose. Indeed, it may be questioned whether its most conspicuous achievement has not been in this direction. Three local sections have been maintained; in New York, Philadelphia, and San Francisco. The meetings have been frequent and informal, and, being preceded usually by a dinner, have taken on the air of social gatherings. The attempt to restrict attendance to members has wisely been abandoned, and the sections are now, practically, convenient units for taking the lead in organizing such meetings and dinners as best fit the local situation. Possibly this phase of the activity has been best developed in San Francisco, where visits of the Directors of the United States Bureau of Mines and of the United States Geological Survey were signalized by complimentary dinners, organized by the local section, but attended by large numbers of engineers who were not members. It is undeniable that a small organization permits development of a bond of union not possible among the thousands who are practically mere subscribers to the *Bulletin* or *Transactions* of the larger Institute.

As to the third purpose of the Society, the formulation and expression of opinion, no results of moment have been accomplished. The Society has endorsed certain general

proposals as to the content of annual reports and has amended its own constitution. Most of the subjects discussed have never come to vote, or were voted on after any action ceased to be significant. It has been extremely difficult to get enough votes cast to either accept or reject a proposal, and at present certain matters about which there is no real division of sentiment, in one case only one negative vote having been cast, have been sent back for a second ballot, in order to secure enough affirmative votes for passage. This difficulty in securing expression of opinion we believe to be due to two causes: the cumbersome method of voting, and the denial of the right to local sections of expressing any opinions whatever. Change in the method of voting has been proposed, and in time will probably be effected. Change in regard to rights of local sections has also been suggested, but there is less hope of this being made.

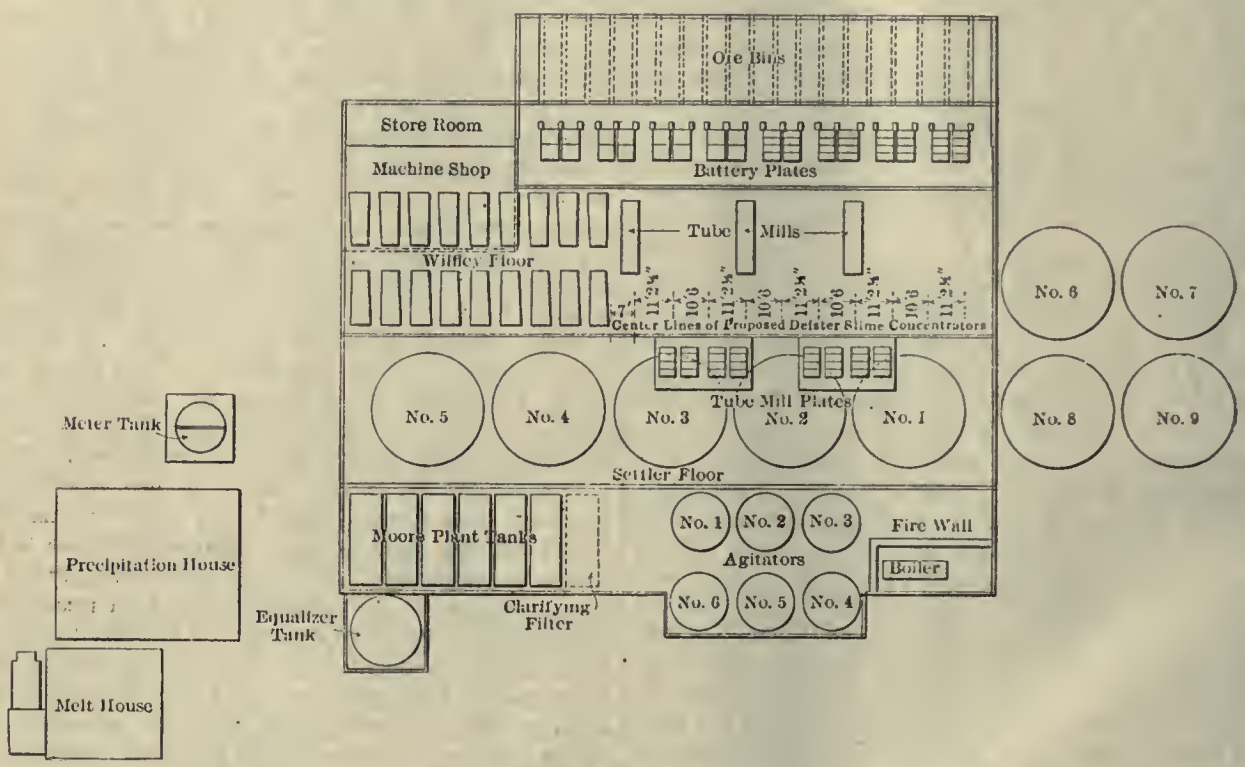
The San Francisco Section recently appointed a committee to consider this matter and to propose some modification of the by-laws. After due deliberation it was proposed that local sections should have the right to make public their conclusions regarding questions of public or professional interest upon which they had acted, provided that due notice of the proposed discussion had been given all members in advance, that the resolution should be adopted by a two-thirds vote, that it should be approved by the members of the council belonging to the Section, and that the conclusions should be published as those of the Section only. This proposal, with others, was considered by a committee of the council of the Society which reported: "We are unable to recommend, however, that any Section shall have the right to make public its conclusions upon any matter under any circumstances." The names signed to this report, those of Messrs. J. Parke Channing, H. M. Chance, and W. R. Ingalls, are such as to give it weight and assurance that the conclusion was not hastily reached. None the less, we venture to differ with the committee as to the conclusion. The reasons assigned for taking such radical ground are: (1) that the membership of the three organized sections is vague, and, in the aggregate, less than a majority of the members of the Society; (2) the Society is national in its scope and aims, and has no concern with local questions; (3) it would be chimerical to expect the general public to discriminate between action by the Society as a whole and action by a local section thereof; (4) since a majority of the members of the Society can never be affiliated with any local section, it would be unfair to commit the name of the Society to anything that the whole membership had not considered. As to the first, it is evident that it would be easy to remove any vagueness that exists as to local membership, but the proposal of the San Francisco members contemplated due notice to all members resident in the area represented by the Section. As to the second objection, it is to be admitted that difficulties may arise as to what is a local matter. When a committee from the New York Section assisted in the admirable work of cleaning up the Curb, there is some question whether that was more local than national in its effect. When, too, by the chance that a majority of the executive committee of the Society resided in New York, Mr. E. G. Spilsbury was duly authorized to act for the Society in protesting against certain legislation pending at Albany, the matter was local, but had national bearings. When, however, an equally important bill relating to mine inspection was pending in California, owing to the accident that a majority of the executive committee do not live in the West, though an equal number of members of the Council are members of the local Section, there was no means of doing the same thing that had been done in New York. If three members of the Council, selected by their associates to form an executive committee, have sufficiently the confidence of the members of the Society to authorize action in regard to New York State legislation—and we wholly approve of the action taken—why should not three other members of the Council, following notice, debate, and approval by three-fourths vote of a local section, be authorized to make public a conclusion regarding a problem regarded by them as local? To deny this right to "any Section" under "any circumstances" is to assume that by process of election the wisest men are always selected for membership in the executive council; a belief that places more faith in elective processes than in democracy. If there is one place where democracy should be supreme, it is within the ranks of a professional society. To the objection that the public would not discriminate between action as a whole and action by a local section, we would reply that we have no such low opinion of the discrimination of the public, provided a fair announcement be made. No one confuses a bill passed by the Senate, with a law, which must pass the Senate and House and be approved by the President. Declaration of California Republicans for progressivism does not seem to have committed the Republican party in Pennsylvania or throughout the Nation; and no one who thinks of the matter at all, supposes it has. The Philadelphia Section of the Mining and Metallurgical Society itself, has formulated and published an admirable code of professional ethics; but its adoption by that Section has not committed the Society as a whole. The futility of the position taken by the committee makes it almost ridiculous. As the matter now stands, any section of the Society can meet, debate, and pass a resolution. In due time it will all be printed in the bulletin of the Society open to the whole world. Suppose some perverse section chances to pass a resolution relative to some matter judged by the executive committee to be local, what is to be done? Shall all reference to the matter be suppressed? If it is not sufficiently national to warrant a place in the bulletin, are the local members to be told they wasted their evening, and are they to be forbidden giving any publicity to what seems to them of first importance? This again assumes a superior intelligence taken on with the vestments of office; an assumption we believe contrary to fact and which the present members of the executive committee would be first to disclaim. The members of the Mining and Metallurgical Society, as we know them, are in all parts of the country able and thoughtful men. They are not men to be content to meet and merely talk, or to assemble and go through motions. They will not waste time over trifles, and the mature conclusion of any dozen of them is worthy of, and should have, the fullest publicity in the form, and at the time, most likely to accomplish good. To grant this in no way commits other members of the Society who may, for the best of reasons, differ as to the conclusion adopted. No one city, no one section of a country as large as ours, can be the centre of things professionally, and best results will be accomplished by giving the widest possible latitude for formulation and expression of local opinion. This in turn will lead to really sound general opinion, but unless the avenues of discussion be kept wide open, the burden of inertia now evident whenever the Society attempts to record a vote, will never be overcome. We have no quarrel with what the Mining and Metallurgical Society has done, but we do protest that it has done little and regret that the form of organization precludes its doing more. Since committees have been appointed to consider the desirability of consolidating the Society and the Institute, we deem the matter of sufficient professional interest to warrant our remarks as well as a discussion next week of the new plans of the American Institute of Mining Engineers.

The Liberty Bell Mill

By Charles A. Chase

*The metallurgical practice here has frequently been described, and I will try not to dwell on well known features. The accompanying flow-sheet and ground-plan need no explanation, showing as they do the proper relations between the following units of equipment:

1. Eighty 850-lb. stamps with suspended Challenge feeders.
2. Sixteen copper amalgamating-tables, each 8 by 4 ft., with three 1-in. drops.
3. Four Richards vortex (hindered settling), 3-spigot classifiers.
4. Eighteen Wilfley tables and 10 Deister No. 3 tables.
5. Three Abbé pattern, 5 by 22-ft. tube-mills, the feed thickened by Dorr classifiers, or diaphragm cones.



PLAN OF LIBERTY BELL MILL.

6. Eight amalgamating-tables, of the size given above.
7. Nine Dorr continuous settlers, 33 by 11 feet.
8. Six Hendryx type agitators, 17 by 11 ft., above the 45° cone.
9. One equalizer vat, 20 by 15 feet.
10. Moore filter-plant, 7 vats, each 9 by 27 ft. in area, and 8½ ft. to the coning.
11. Zinc-shaving precipitation-plant, capacity 1200 cu. ft. of zinc.

The stamp-battery was originally built on wood blocks, with the usual framing and front horizontal drive from clutch-pulleys on the line-shaft. The wood foundations have been replaced by concrete, and the framing is simpler. The post rests on the concrete, only a piece of 6-ply Gandy, or similar, belting intervening. The results have been perfect. Ten stamps have heavy Allis-Chalmers anvil-blocks, the other lighter Denver Engineering Works 'sub-bases'. There is no apparent difference in results, and the lighter construction is cheaper. Globe stem-guides have been reasonably satisfactory through many years, but are now being replaced by the simpler and stronger Pacific guides. Shoes, boss-heads, and tappets are of chrome steel. The cams are of the Allis-Chalmers Blanton pattern. This Blanton fastener is also used for the bull-wheel. Dies are of east iron, from the local foundry, containing a large percentage of steel scrap.

The horizontal battery-drive through clutch-pulleys was unsatisfactory and solid pulleys were substituted, it being cheaper and easier to cut an occasional belt, in case of desiring to stop a 10-stamp section for considerable repairs, than to maintain the clutches. The feeders are operated by the feeder-wheel mechanism, shown in the illustration, a good device, patented by the mill foreman in 1900. Battery screens have recently been of two patterns: 14 by 14 mesh, No. 22 wire, aperture 0.043 in.; and 16 by 3 mesh Ton-cap, 0.039 aperture, which yields a finer product and a larger tonnage than the former, having heavier wire and the same aperture blinded. It seems that the wire must be light enough to spring readily under the impact of the splash. A screen analysis of battery pulp shows: On 40 mesh, 24.4%; on 60 mesh, 10.9%; on 80 mesh, 5.9%; on 100 mesh, 6.3%; on 200 mesh, 9.6%; through 200 mesh, 42.9%. Some 38% of the battery pulp is flocculent. The power charged to the battery amounts to 160 horse-power.

The ore is stamped in cyanide solution. The recovery by amalgamation is materially less than in previous years of water-amalgamation; it is more expensive in both labor and material and requires more skill, and the consumption of copper is considerable. Muntz-metal, which has proved a satisfactory substitute elsewhere, has not been successfully adapted here, taking on a hard, glassy surface. The plates are kept rather wet, and any drip of quick is caught in a trap. From a month's run the results of amalgamation were: from battery-plates, 80% of all amalgam, yielding 29% bullion, 0.408 Au, 0.551 Ag; from tube-mill plates, 20% of all amalgam, yielding 23% bullion, 0.153 Au, 0.825 Ag; the first plates have a grade of 2¼ in. per foot, and the second plates 1⅜ inches.

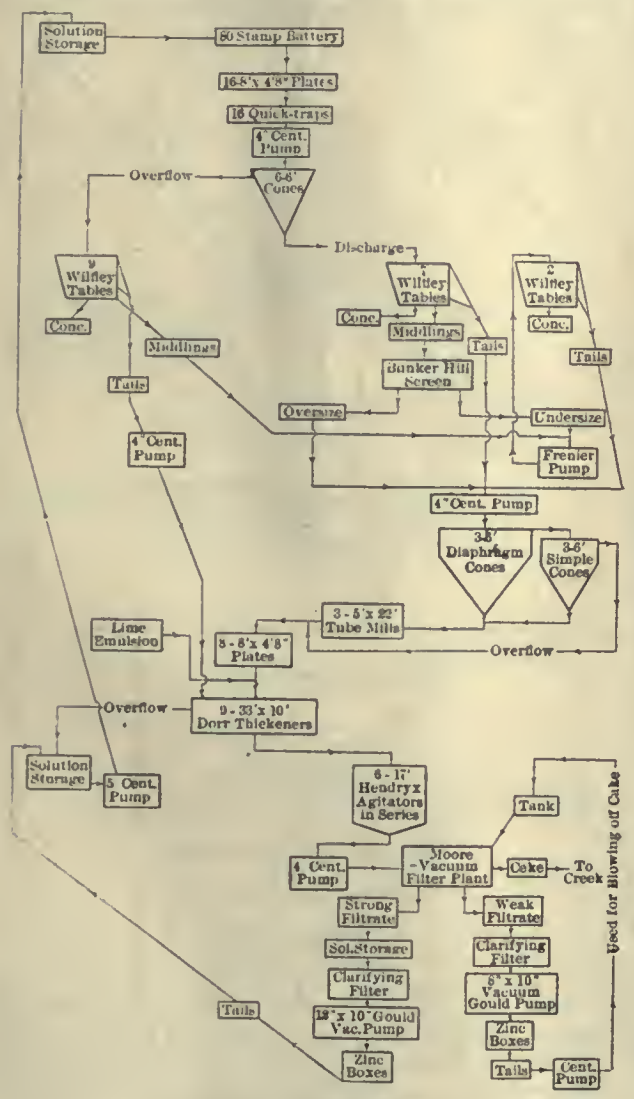
The concentration scheme is only now assuming definite form. Nine Wilfley tables take the underflow from the Richards classifiers, two take the middling, after removing the coarse on a Bunker Hill screen, and seven take the overflow, after thickening in six 6-ft. cones. The 10 Deister tables are to take the reground sand from the tube-mills. Any oversize tailing from these latter tables is returned to the tube-mills.

This arrangement seems to represent a reasonable economic limit. Further expansion of plant would yield returns on the investment relatively slowly. The great im-

*A portion of a paper to be presented at the San Francisco meeting of the American Institute of Mining Engineers.

pediment to perfect work is the argillaceous slime. Coagulated by the alkaline solution, it is exceedingly buoyant and sustains coarse material, both sulphide and sand, until dilution is carried to extreme limits. This scheme represents the lesser of two evils. For three years concentration was applied to the tailing, after filtration and dilution with water. An extensive area of canvas with Wilfleys and vanners gave poor returns, and it was evident that the sulphides, probably concentrating to some extent in the tube-mills, were ground so fine as to be irrecoverable. Moreover, what was caught was so high grade as to suggest re-precipitation of silver on the pyrite. The extraction of gold was comparatively good.

That amalgamating is still carried on has occasioned some adverse comment. It is recognized that the absence of this step would materially cheapen and simplify the milling. Sixty stamps, at most, would be required to crush the full tonnage through the coarser screens that could be

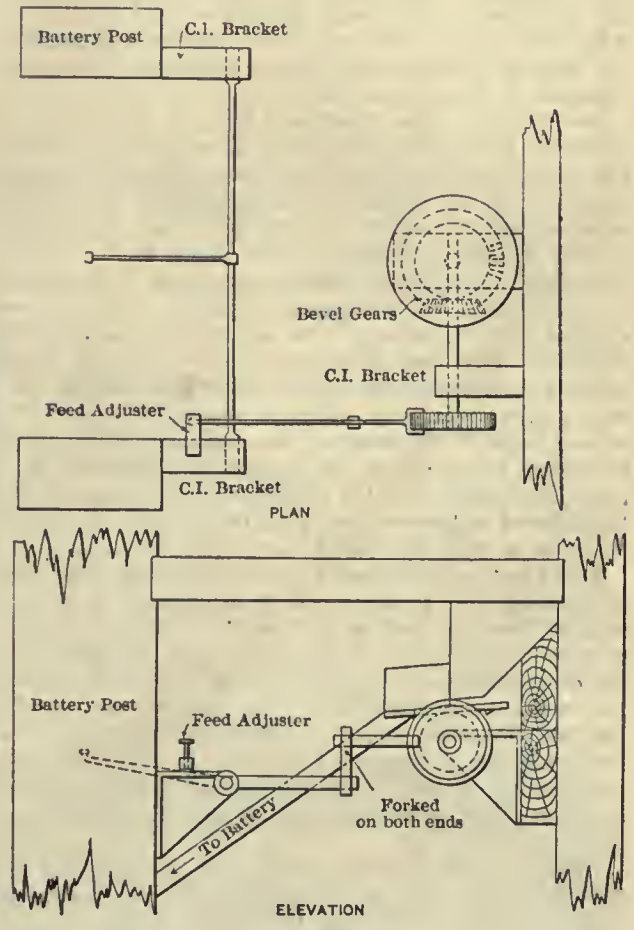


FLOW-SHEET, LIBERTY BELL MILL.

used. It has been stated that the gold occurs irregularly in the ore, and hence is likely to be coarse. This gold would make an unwelcome element in the concentrate, which has not as yet been made amenable to local treatment. A streak of gold on the tables would be a constant source of danger, and the product would be spotted and difficult to sample for sale. Were it feasible to concentrate successfully after regrinding, the battery plates might well be done away with and the coarse gold allowed to go into the tube-mills with assurance that it would be ground and taken into solution; but that concentration after regrinding is not good practice here seems to have been amply demonstrated. The power charged to concentrating is 30 horsepower.

Regrinding.—The tube-mills are of the Abbé type, tire-mounted and with spiral feed. The tire-mountings were designed by the company's engineers, are amply rigid, and also give complete protection against possible end-travel of the tires off the rollers. The tires, both on the mill and on the supporting rollers, are of forged steel and promise indefinite life. The drive is by 50-hp. motors, belted to counter-shafts which in turn drive through heavy friction-clutches to the tube-mill shafts. The mills start readily with the use of the clutch, showing a maximum starting-peak of 78 hp.; the running-load varies from 45 to 48 hp. The lining is of 4-in. silex blocks, set in cement mortar, with the narrow edge to the wear. It gives a year's continuous service. The grinders are 4-in. imported flints, costing $33 per long ton delivered. The ends are lined with local cast iron, and the discharge is through a grating, which will probably give way to the Neal cone-discharge. A typical screen-test is as follows:

Screen Mesh.	Feed. Per cent.	Discharge. Per cent.
On 40	47.1	0.7
On 80	29.4	11.4
On 100	8.2	9.2
On 200	6.4	22.3
Through 200	8.9	55.4



BATTERY FEEDER.

As nearly as it is determined, half of the total tonnage crushed is reground. The efficiency of the regrinding varies with the excellence of the separation of the slime. Failure to remove this gives buoyancy to the pulp within and the grinding is poor. With this object in view, the above screen-test is not satisfactory. The practice is to force a diaphragm-cone and to care for the overflow of sand in a simple cone in series. The discharge from the simple cone carries slime out of all proportion. This is mixed with the discharge from the diaphragm-cone to dilute it to 48% moisture. The result is to lose much of the benefit had from the diaphragm-cone. It will undoubtedly prove better to combine the overflow from the three diaphragm-cones in a single simple cone and confine the hampering effect of the fine material to one mill; or, better, a Dorr classifier at this point would be admirable. The feed

to the other mills, being then diluted with clear solution, the grinding should be good.

The work of this diaphragm-cone in preparing feed for a tube-mill is remarkable, as the following screen-test shows. The completeness of the elimination of fine suggests the benefits of hindered settling. This is a 6-ft. cone with 60° sides. The diaphragm is 13 in. from the point, with a 1½-in. annular space. The discharge is 1¼ in. diameter.

Screen. Mesh.	Cone Feed. Per cent.	Discharge. Per cent.	Overflow. Per cent.
On 40	27.22	58.95	0.19
On 80	24.82	30.66	8.97
On 100	7.55	5.15	7.44
On 200	8.89	3.42	17.00
Through 200	31.52	1.82	66.40
Moisture	.....	30.80	.....

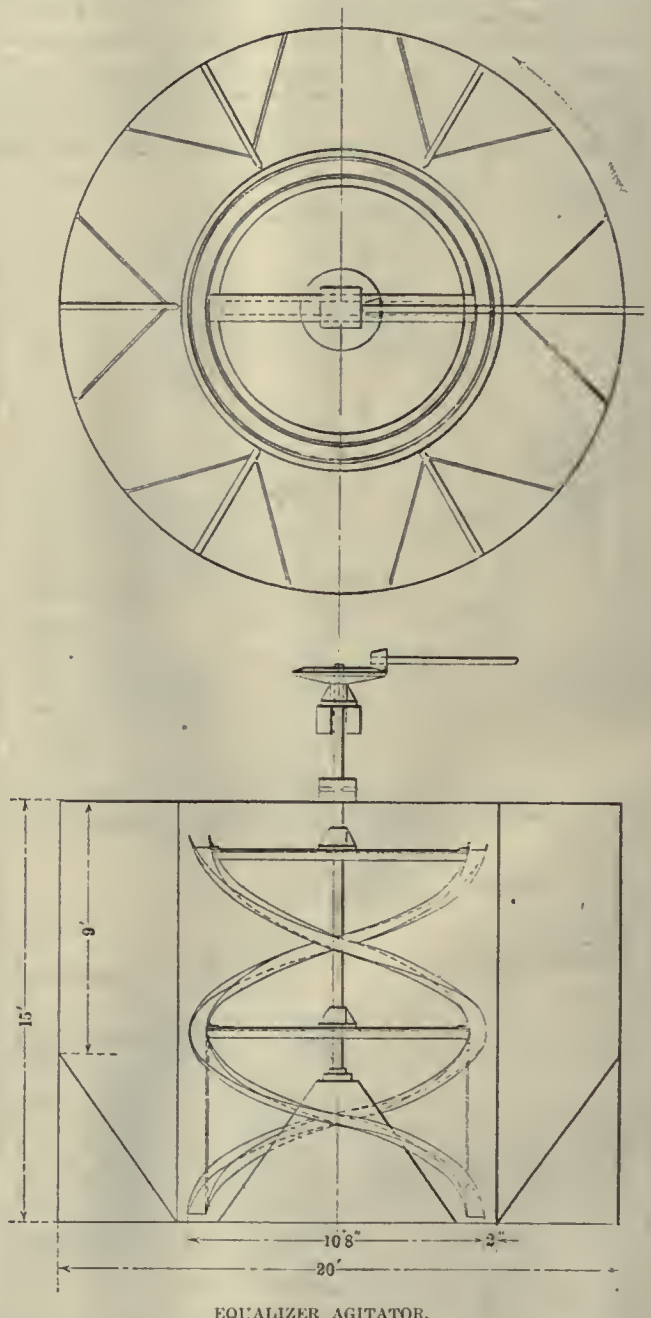
The absence of results from Dorr classifiers is due to the fact that the two machines installed here were the first, after Mr. Dorr's original installation at Terry. They conformed to his pattern neither in area nor in bottom-slope, being built in what space was available, and were overloaded. The results have been good through four years service, but not as good as would have come from the larger machine. The pebbles are fed during the day by the shift-boss, being shoveled into the spiral feed; 135 lb. is the daily charge. The mills are entirely smooth-running, and the cost of maintenance is at a minimum. The power consumed is 43 hp. per unit.

Dorr Settlers.—The latest step of great importance in improving the mill was the change to continuous from intermittent or charge settling in thickening the pulp for agitation. It is not possible to state definitely that certain measured results followed exclusively from this change. Certain definite improvements were shown by the experimental unit, and large improvements have followed the complete change, but at the same time other conditions were changed. The following are the principal advantages thus obtained: First, continuous extraction is obtained where before the solutions were inactive or re-precipitating; second, a given volume of settler space has 25 or 50% increased capacity, operated on the continuous basis; third, extraction going on in the settlers, the addition of a plant for settling has the added value of supplementing the deficient agitator-volume; and, fourth, labor is reduced one man on each of three 8-hour shifts.

This plant, originally of 5 vats, settling the pulp from the ratio of 5:1 to 2.5:1, has been increased to 9 vats, settling from the ratio of 9:1 to 2:1. The increase of solution has come with the addition after the battery of the concentrating-plant, with its great volume of solution for washing and classifying. The four settlers recently installed have been placed out doors, with individual conical roofs and underneath shaft-drive in a conduit, with great saving in cost as against providing the usual mill structure. The power consumed is one-fifth horse-power per unit.

Agitation.—The agitator-capacity was designed with the expectation of using a low-potential electric current to hasten extraction, following the results of extensive experimental work. The plan failed, and, without the current, the provision of space was inadequate. This has been remedied, in large measure, by the addition to the settler-plant, already mentioned. The connecting of all agitators in series for continuous operation was a natural sequence of the adoption of continuous settling. The results appear better, but statistics on which to base exact conclusions as compared with previous charge-agitation are lacking. Some saving in labor of operation and of maintenance is evident. These agitators operate steadily with little attention and very low cost of repairs, but the unit-size is too small for a large-tonnage plant, and the power consumption (6 to 7 hp.) is out of proportion, as compared with Pachuca tank practice or arm-agitation, as carried on at El Oro. No benefit was obtained by spreading the pulp over distributors from the top of the central well, and it is allowed to plunge from the collar of the well. The power consumed is 50 horse-power.

Moore Filter-Plant.—The equalizer, an integral part of the Moore filter-plant, is a simple type of slow-speed agitator (see illustration), efficient for all depths of pulp in the vat and consuming a minimum of power. It has been lately patented and put upon the market as the Gordon agitator. The filter-baskets of 66 leaves, each presenting two surfaces 8 by 6.5 ft. of free filtering-surface, are carried on two 10-in. longitudinal I-beams, which are in turn supported by transverse 6-in. beams which extend to the vat walls. The leaves are of No. 6 (20-oz.) canvas, reinforced on both sides at the bottom of the vertical stitching with a strip 3 in. wide of the same canvas. The



EQUALIZER AGITATOR.

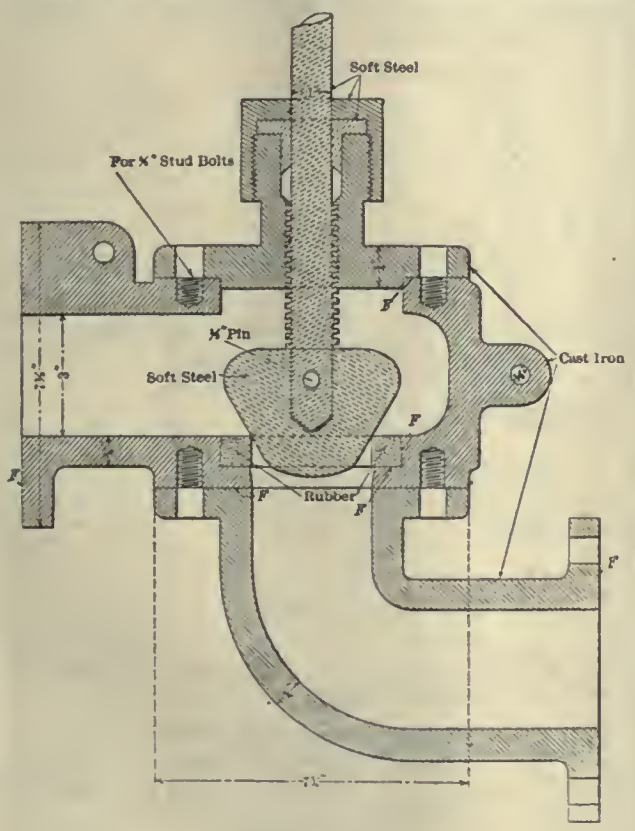
vertical seams are on 2-in. centres, and the wood strips between are ⅜ by ½ in. The frame is of ¾-in. iron pipe on ends and bottom, and the top is of strap and angle-iron. No cocoa-matting or other filter is used.

The leaves are made at the mill, the sewing (No. 4 linen thread, ¼-in. stitches) being by power machine (Singer 7-7), and cost complete $12; new canvas alone in place costing $8. The life of a filter is 18 months. All canvas requires hydrochloric acid treatment at intervals of three months. To do this a wash-water vat is brought to 1.25% HCl (18° B.) and to 140° F., the basket is immersed and the liquor circulated with a wet-vacuum pump. All the canvas in use can be treated within 30 hours. The cost of acid is 0.6 cent per ton of ore.

The lifting of baskets is by hydraulic cranes with cylin-

ders 20 in. by 9 ft., the water at 250 lb. pressure. Connection from the crane to water-main is by a specially reinforced coupling on a short length of metallic hose. The raised basket is held by a safety-catch on the crane, and the transfer is effected by a 10-hp., 3-phase, constant-speed motor, with a 3-armed trolley above. Transmission from motor to crane is through a Dodge multiple-disc friction clutch on the motor shaft. The service is severe, but the clutch does well. The vacuum connection from the basket is through a 3-in. hose to a pipe turning in a stuffing-box, and is maintained throughout the transfer.

The greatest single step in perfecting the plant was the change from the common wet-vacuum pumps to a combined dry-vacuum and wet-vacuum system; all entrained air is taken out at the upper end by a dry-vacuum pump, an 8½ by 10-in. vertical duplex air-compressor, and all solution at the lower end with centrifugal pumps in a sump 23 ft. below the top of the filters. Some leaks in canvas will occur, and sand sufficient in quantity to destroy a positive wet-vacuum pump in a few hours is harmless



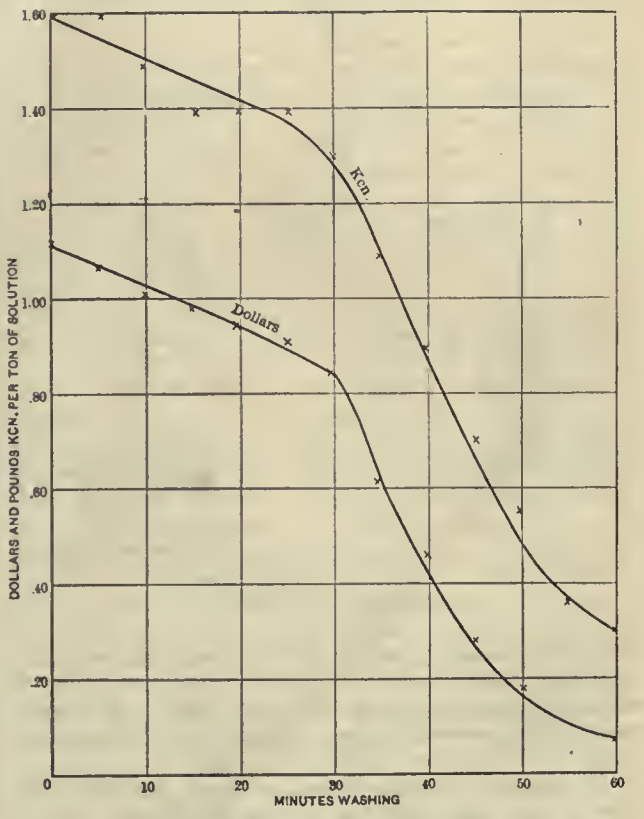
VACUUM-VALVE.

to the centrifugal. Between the dry column at one end and the solution column at the other runs the main for strong solution. Parallel to this and leading from the same dry column runs the weak-solution main, but to a different solution column and pump. Any basket may be connected with either vacuum main, or with the blow-off water-main without disconnecting the hose. The vacuum never fails, being held at 19 to 20 in., near the maximum attainable at the altitude of the mill. To make this possible an excellent valve was designed (see figure). Its appearance is that of a globe valve, and its merit lies in seating an iron cone on a hard-rubber ring of square section. It is quite impossible for sand to lodge on the ring so as to interfere with closing.

Filtration is accomplished in two groups of three vats each, the central one for loading and the two on either side for displacement in water. Basket No. 1 loads in the centre vat and is moved to the wash-water vat at the right. Immediately thereafter basket No. 2 moves from wash-water vat at left to loading vat. The cycle is thus: Loading, 50 min.; transferring and drying, 5 min.; displacing and discharging, 45 to 55 min.; transferring, 5 min. Each load is a ¾-in. cake, weighing 2.75 lb. dry per square foot, or 9 tons per basket-load. This gives a capacity of 108 tons per basket per day, corresponding to 432 tons for the plant. Vertical uniformity of loading is secured by the use of three air-lifts, which elevate pulp from the bottom of the vats and discharge it over the top.

The practice of displacing at once in water, without an intermediate wash of barren weak solution, can be approved ordinarily only on the assumption of good displacement and low-strength solutions. Displacement is efficient, but the solution (1.6 to 1.75 lb. KCN at this point) is higher than was planned when the plant was designed. A factor that enters the special problem here is the 8% of moisture brought to the mill in the ore. Average results in washing are shown by the accompanying curve. The cake, partially dried, contains 33% moisture, not taking into account the solution in the pipes and channels, which is difficult to determine, but which must approximate one ton. The cake and passages thus retain a total of 5.5 tons of solution containing 8.8 lb. cyanide and $6.16 in gold and silver. The rate of displacement is 0.15 ton per minute.

In filtration there are two principal ends to serve: (a) to



WASHING CURVE, MOORE FILTERS.

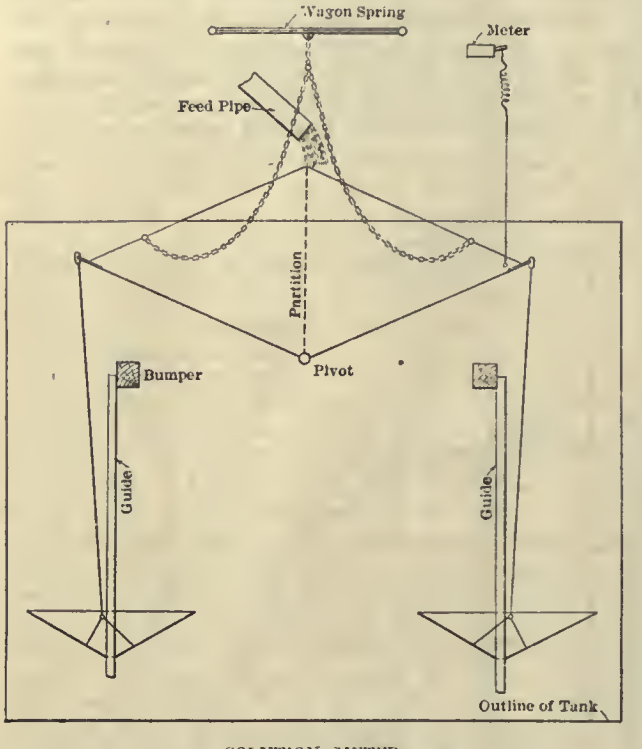
recover enough strong solution to restore the mill stock; (b) to recover the dissolved gold and silver, and that in solution of such strength as to insure precipitation. Were the ore dry on entering the mill, 36 min. filtration would be sufficient. As the solution drawn in this period contains 7.72 lb. KCN, the efficiency of displacement is 87%, measured in cyanide. As it contains $5.08, the efficiency is 82%, measured in metals. It seems fair to accept 84 or 85% efficiency.

The mechanical loss of cyanide by dilution is that which cannot be restored to the mill stock. The fact that 35 tons of water is brought to the mill with the ore makes it impossible to secure the maximum theoretical efficiency given. From each basket-load the solution recoverable is $(5.5 - 0.8 =)$ 4.7 tons, containing 6.48 lb. KCN. The combined mechanical loss is therefore $\frac{8.8 - 6.8}{9} = 0.22$ lb. KCN, or 4.7c. per ton of dry ore.

In 55 min. washing, the recovery of gold and silver is $5.93, the apparent loss being 2½c. per ton of dry ore. This seems to be a maximum figure; washing to 70 min. showing almost complete removal. Regular sampling of the solution in washed cakes is not convenient, but, so far as done, it shows 1 to 2c. The loss in cyanide by dilution being so small and the recovery of dissolved metals being

complete, the only remaining consideration is the low average strength, 0.75 lb. KCN, of the weak solution. Solution at 0.9 lb. KCN precipitates well. The use of a barren wash would insure this strength in the weak solution. On the other hand, 1c. per ton of ore will restore the few tons of weak solution to strength on the infrequent occasions of poor precipitation. It seems that added costs in depreciation, operation, and maintenance would offset any gains from an intermediate wash.

The weak solution after precipitation is used at low pressure, to force the cake from the filter, submerged in wash-water. An advantageous change would probably be to perform this with air and thus return a more nearly dry basket to the loading vat. The removal of tailing is



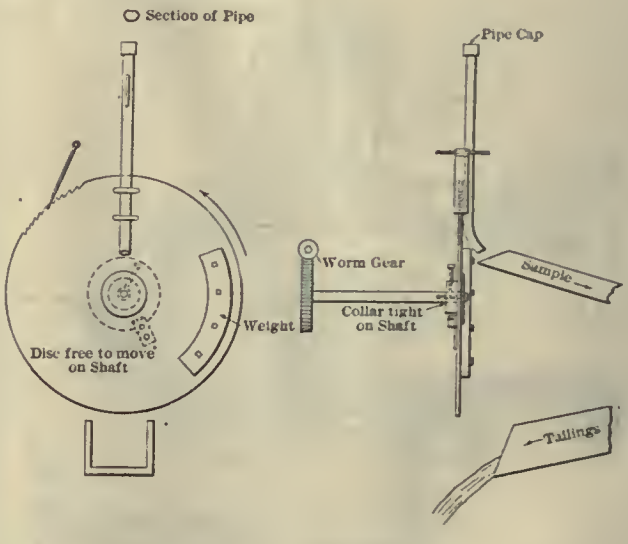
SOLUTION METER.

wholly automatic, by reason of the excess of wash-water available. The vat walls run down to three points, across which discharge single jets of water from ¼-in. nozzles, carrying the descending mud through ½ to ¾-in. orifices in the walls opposite the jets.

The operation of four baskets has been described. The fifth is used as a clarifying filter in the seventh vat. All solution, whether decanted or filtered, though apparently clear, requires clarification to insure clean zinc-boxes. In this service the canvas acquires a remarkably fine impervious and tenacious coating. To remove this the basket is returned to pulp filtration after 10 to 14 days. At times a coat of pulp has been gathered on the canvas before using it to clarify, but this seems an unnecessary refinement, which reduces its capacity. The power consumed is 30 horse-power.

The Zinc Precipitation shows little that is unusual. The results are usually excellent with average heads of $1.25 and tailing of 1 to 2c. The flow of solution is 0.7 ton daily per cubic foot of zinc, and 2.4 tons per ton of ore milled, $^{3}/_{10}$ of the whole mill solution being precipitated. All the solution is metered above the gold-solution vats by a mechanism devised from a common tilting-box tailing-sampler (see illustration). The pans or pipe guides are always submerged, and, in the manner of dash-pots, steady the movement of the box. Being placed over the vats, any splash is accounted for in calibrating. Each cycle is registered by a counter. The zinc-lathe is home-built and has a capacity of 700 lb. to 0.001 in. per 8-hr. shift. As cut the zinc is gathered on revolving arms in skeins which fit the boxes. The sludge is gathered semi-monthly, treated with sulphuric acid, washed, dried, and melted. Always high grade, it has recently reached a maximum of 92% bullion. The drying-furnace is of the cast-iron muffle type, and the melting is in No. 150 B. L. crucibles in coke furnaces. The charge for power is 7 horse-power.

Pumping Plant.—The handling of ore and solution necessitates much pumping. This is done with improved Byron Jackson slime-pumps. The pumping units are in duplicates for pulp. The liners used are ¼ to ⅜-in. cast iron. Manganese steel is to be tried. As it stands, the record shows this to be a good centrifugal pump. The life of the liners varies with the thickness of the pulp and the proportion of clay to sand. The tube-mill feed with nearly clean sand gives the shortest life, and the agitator discharge, very thick and with all the clay, gives the longest. Notwithstanding this good service from the centrifugal pumps, I have been for some years of the opinion that the proper pumping equipment for this mill would be a low-pressure compressor with air-lifts for almost all transfers, and to replace the mechanical agitation. The displacement of motors, belting, and shafting, with their need of skilled supervision, would far outweigh the loss of efficiency in the air-lifts. The milling operations would be characterized by extreme simplicity.



PULP SAMPLER.

Use of Chemicals.—The mill-sheets show this average in cyanide and protective alkalinity:

	Battery Head.	Second Plate Tailing.	Filter Heads.	Consumption.
KCN	1.75	1.64	1.50	1.48
P. A.	2.32	1.44	1.92	.....
CaO	....	....	....	7.5
PbO	....	....	....	0.33

The mixed salt, 99% KCN, is used, no advantage being evident at first in trials of the 130% salt, but a recent concession by the makers has led to further trial with the 130% salt, with better results. The figures given are in pounds per ton of solution. Durango lime is used and the figures are in equivalents of caustic soda. Until September 1909 lead acetate was used, ¼ to $^{3}/_{10}$ lb. per ton of ore being added at the agitators. Since that time litharge, ⅓ lb. per ton, has been added with the tube-mill feed. An apparent improvement of 5% in silver extraction from the charge is based on inadequate tests.

Cost of Operation.—The operating costs for the period from the beginning of operations with the present type of plant are given below. I do not attempt to reproduce more than total department costs. The expense readily chargeable to the various departments is so disposed and the reason for leaving the other items as a general charge I believe is clear. The general charge for power is the cost of pumping between departments. The first two years were marked by many mechanical difficulties. The benefit of the abandonment of the canvas plant and the change to continuous settling was shown during 1909. The increase in freight, treatment, etc., in 1910 is due to the increased tonnage of concentrate. The balance-sheet and

summary of the mill work were given on page 742 of the *Mining and Scientific Press*, May 27.

These figures are given as a service to the public, following the practice of Arthur Winslow in making public his annual reports on the mine. It is hoped that others may derive from them some return for the benefit that the author and his associates have derived from published accounts, letters, and free access to plants elsewhere. Further, it is hoped that the figures may serve as a warning in some cases and a source of encouragement in others. Certainly, one embarking on a new enterprise under similarly hard conditions can get some measure of the obstacles likely to be encountered. On the other hand, the great improvement of the past two years shows what is possible. This result is primarily the culmination of many years working toward the re-treating system and concentration of operations in mining; a result delayed principally by the harassing labor conditions of 1902-1908, and, in part, by the lack of sufficient early development.

OPERATING COSTS, LIBERTY BELL MILL.

Inasmuch as this mine is situated in a part of the West noted for its high freight-rates, living-costs, and wage-scales (in this case the mine and mill averaging $3.60 and $3.75, respectively, per 8-hr. shift), it furnishes an interesting comparison with the results secured with the alleged 'cheap' labor of Mexico. This comparison is apt, because in its requirements metallurgically the mine is more nearly comparable with the practice at El Oro and Guanajuato than anything north of the line. I wish in closing to acknowledge the courtesy of Mr. Arthur Winslow in granting me permission to publish the many details given, and the valuable assistance of Messrs. W. H. Staver, M. L. Anderson, W. E. Tracy, and H. G. McClain, all of Telluride, Colorado, in collecting drawings and special information.

Telluride, Nevada

By H. C. Cutler

The new Nevada camp of Telluride is situated in the Battle Mountain range, Lander county, near the head of Willow creek, and some 25 miles from the town of Battle Mountain on the Southern Pacific railroad. There is a good wagon-road to within a mile and a half of the camp, and an excellent trail for the rest of the distance. It is only 16 miles from the railroad by the way of Valmy, and a movement is on foot to construct a wagon-road to this point.

The main property and the only one on which any development work has been done, has recently been incorporated into the Dollar Mining Co. by Thomas Kearns and associates. Some stock has been sold, and prospecting work started on a larger scale. The vein was found in the latter part of 1910 by J. Hutchins, but owing to the heavy snows in that section, little work was done on it, and the discovery was not made public until this spring. The camp is situated at an altitude of about 7500 feet; water is plentiful and wood is scarce.

The neighborhood has been thoroughly staked, and several promising veins, showing fair ore, have been uncovered. With the exception of the main find, little work is being done in the district, the present owners preferring to wait for capital to come in and take the chances. This area was mapped by the Fortieth Parallel Survey as Webber quartzite, and the vein on the Dollar property is apparently a quartzite; in some places altered to a glassy quartz, in others, soft, decomposed, and stained by iron oxides. It shows a width of from 8 to 25 ft. and lies between two belts of slate—a hard black slate on the foot-wall, and a soft, light-colored slate on the hanging wall. The formations dip about 45° to the northwest. A number of cuts have been made on the surface, exposing the vein for 100 ft. In one of these cuts a rock, probably eruptive, was exposed, but its extent and whether it occurs as a flow or as an intrusion, is not now known. It is likely that the ore is due to its presence.

The ore is an altered quartzite carrying free gold, with but little silver and occasional crystals of tetradymite or telluride of bismuth. Frequently free gold is found, imbedded in the crystals, showing that the deposition of the two minerals was simultaneous. Near the surface the tetradymite is more or less oxidized, and the rock shows a greenish stain, which might indicate a trace of copper.

The discovery-shaft was only down some 8 ft. when the present company acquired the property. Since then it has been continued to 30 ft. On the surface, assays ranging from $2 to $500 were obtained, and from present indications it seems quite probable that ore of a fair milling grade will be developed. A townsite has been located, but the necessary elements for a Nevada boom are lacking, and consequently the camp is not growing very rapidly. The now nearly deserted camp of Bannock is only five miles distant. The main things needed in Telluride are money and work.

Nickel is chiefly produced from nickel copper ores. These occur in many places, but the best known desposits are at Sudbury, Ontario. The nickel and copper are separated by smelting with 'salt cake' giving 'top' and 'bottoms,' of which one contains more copper and the other more nickel. The blister copper finally produced contains some nickel and the nickel some copper; their final purification is effected by electrolysis. The nickel and copper together form 'monel metal,' a new valuable alloy.

Unavoidable Errors in Sampling

By Morton Webber

Much has been written recently in regard to unavoidable or latent errors in mine sampling, and also in respect to obvious errors arising from carelessness and ignorance. As to the former, my own digest and corollaries may be of interest, but no attempt will be made to deal with the latter class. Mine sampling, no matter how carefully done, usually indicates a higher metal content than that shown throughout an adequate period of commercial ore treatment, affording data of actual results in mill yield, plus residual contents. In the South African banket, where thoroughness and accuracy of sampling is probably second to none, the mill yield plus tailing content is invariably from 15 to 25% short of the average indicated by sampling. In the premier lead mines of Australia the discrepancy is at least 10%. The results from four well known gold mines show an unaccounted difference of some 12%. These mines are situated respectively in Mexico, Colorado, Australia, and India, and the fluctuation from one to another is not more than 4%; with the above average.

In a mine valuation the conditions will generally fall under one of five classes. I will endeavor to enlarge and explain each respective class; but it should be understood that many mines will belong to a combination of two or more of the classes; and not to any one alone. (1) Mines where the average value is mechanically reduced, but where the unaccounted-for metals may be subsequently recovered; (2) mines where there exists an unrecoverable loss; (3) mines where sampling indicates a fictitious high value; (4) mines where sampling results in an incorrect subnormal value, conclusive proof of these two being afforded by subsequent commercial results; and (5) mines where sampling is of no value. In narrow veins where the breaking of waste rock is necessary, the ore going to the mill will be reduced in grade. Even if sorting is carefully done it is impossible to keep all the waste out of the mill, especially if the enclosing walls are soft; yielding more or less fine. In a narrow vein it is customary to allow for this, but my experience is that such an allowance is generally insufficient. In veins of even normal width it is usually impossible to mine without the inclusion of some waste. In such a case the discrepancy in metallic content may be considerable, owing to the fact that no hand sorting may be employed. This discrepancy will largely adjust itself when the mine or stope is worked out, as the decreased value per ton is compensated for by the greater tonnage crushed. But the valuating engineer will, if he is wise, when computing his factor of loss, largely disregard this; as it will be difficult to explain to those not versed in valuation, that the mill results, while not appearing at the moment up to expectations, will adjust themselves at some future date. In a mine of considerable length of life it would obviously be a patient wait.

In mines where filling is necessary, and also in cases of underground sorting, there is always a loss in the waste, even where boarding is used. This may be a tonnage loss rather than of value per ton, or possibly a combination of both. In either case it is a loss of marketable metals which the mine valuer should be careful to deduct from his estimate. Where the metal contents of ores are in sulphide form, the sulphides are frequently more friable than the gangue. In consequence, the samples will contain an abnormally high proportion of ore. Discrepancies of this class are more usual in copper and the baser metal mines, but in the case of a gold mine, where the gold is associated with friable sulphides, this error should be very carefully considered, as it may result in an estimation out of all proportion to subsequent results. Where there are two sulphides in the same ore, one hard and dense and the other soft and friable, the latter sulphide will break more easily in sampling and will therefore be abnormally represented in the valuation. If the major values are in the hard sulphides the issue is liable to be unfair to the property. I recently examined a large copper mine where the ore was chalcopyrite. There were two distinct types of this ore in the mine, intimately associated. The ore that carried a considerably higher copper content was hard and dense. The lower-grade ore was soft, friable, and easily disintegrated. In this case some allowance would have to be carefully made to compensate the sampling error, which was unfair to the property. There is a class of mine where the valuable minerals occur like currants in a pudding. In this class no confidence can be placed in an assay map, no matter how close a sampling unit may have been chosen. The results will either be high or low; but certainly not correct. Innumerable examples exist where an assay plan would have shown the majority of the samples as unprofitable, yet the commercial results have afforded conclusive proof of undervaluation. This class is not composed only of little-heard-of precious metal mines, such as gold and silver sulphides, for the famous base-metal mines of Missouri and the great copper mines of Lake Superior are a more or less analogous class. The only method of valuation which in this case would appear reliable would be based on authentic records of past yield, in combination with competently selected representative ore-parcel tests of the remaining ore in the mine.

An attempt to tabulate the percentage of error under the relative heads discussed and apply the results to specific cases, would be to mar facts which have taken many years to collate, with the spoofery of the charlatan. In a mine examination the engineer must use his own judgment, and what has been written is intended to enable him to arrive at a conclusion based on sound premises on individual conditions. The most that should be said is that in the great majority of cases sampling will overestimate actual conditions. The amount of error will vary from 5 to 25%, the average being apparently 12%. Cases giving a subnormal result are decidedly in the minority, and before any addition is made to sample returns the facts should be thoroughly understood.

Nature of Permissible Explosives

By Clarence Hall

*The energy developed by the detonation of permissible explosives, like other high explosives, depends on the change of the small solid particles and liquids of the explosives into large volumes of gases, and the rate of detonation or the rapidity with which these gases are formed. To meet the varying coal-mining conditions in this country the manufacturers have formulated explosives varying in rates of detonation from 1447 to 4439 metres (4746 to 14,560 ft.) per second. It is evident that for certain work, where a shattered effect is desired, as in driving through rock, or producing coal for coking purposes, the explosive reaction should be rapid, and permissible explosives should be selected from the list having a high rate of detonation. In a similar manner a suitable permissible explosive for use in soft friable coal, and especially so when lump or steam coal is desired, should be selected, which develops its gases at a slow rate in order that the pressure developed will be more prolonged. I have been informed that the coal operators of West Virginia are overwhelmed with agents of permissible explosives with their various claims of efficiency. To establish their claims it means that demonstrators must conduct a series of experiments over a considerable period of time in the mines. In several instances in mining bituminous coal it has been found that permissible explosives containing only 20% of nitroglycerine have given better results and produced better coal than those made after a similar formula containing 25% of nitroglycerine. The physical tests of explosives, such as in the gallery, rate of detonation, strengths of explosives as determined by lead blocks, gauges, ballistic pendulum, height and duration of flame, will be published as Bulletin No. 15, Bureau of Mines.

*From an address delivered before the West Virginia Mining Institute.

Triangulation Applied to Mines

By E. E. Barker

Most of the engineers of the larger mining properties throughout the country have, for convenience in their work, usually laid out a system of rectilinear coördinates, by which the position of a given point is easily determined. Some have used the scheme of triangulation, while others have depended on the latitude and longitude differences, as calculated from the ordinary traverse. It is my aim, in the discussion that follows, to set forth the facts regarding the condition of claim and section corners as I have found them, and to show why a system of triangulation is almost indispensable on a valuable mining property.

The chief value of such a system is the ease and accuracy with which all the claim corners, and especially the boundary posts, are permanently referenced, that is, tied-in by survey from substantial stations so that in the event of their destruction or temporary removal, their correct position can at once be absolutely determined. In the patent survey of mining claims the office of the Surveyor General now demands that all traverses, including all the exclusions to other claims, and areas formed by the intersection of claim lines with section, county, and State lines, as well as the traverse of the claim itself, close within a maximum limit of one foot in two thousand. In past years such accuracy was not required, and many patents have been issued in our older camps on surveys that would not begin to come within that limit. I have in mind an old patent in the Globe district, Arizona, where the end lines, although parallel in the survey notes, were fully 10° from being so in the field, and one side-line, while supposed to be 1500 ft., measured but 1470. Another requirement in patent proceedings is the tying-in of one of the claim corners to the nearest section or quarter-section corner, and which, in the case of the subsequent destruction of all the corners and their immediate references (if there ever were any), would be the only means by which the position of the claim could be re-determined. The necessity for taking steps to improve the shameful condition of our section and quarter-section corners cannot be too forcibly brought to the attention of the proper government head. Each section corner, in our well developed districts, at least, should be substantially monumented and permitted to assume some of the dignity of the important reference that it is.

Stories have often been told of the manner in which the pioneer 'Knights of the Transit' ran many of their lines; in the case of the subdivision of townships, usually by contract, with the work seldom inspected. Of one it is said that in order to eliminate errors in his estimates he would guess at twice the distance and divide by two. Of another, that he was fond of a certain brand of Havana cigars. Before each day's work he would mark a number of these at regular intervals, previously determined by the distance his mount would travel in a given time. As the ash of the lighted cigar reached each mark in turn—representing a quarter of a mile in distance—he would dismount and establish his quarter-section corner.

While these are exaggerations, the condition of section corners in the older surveyed districts, both as regards accuracy in location and permanency, is deplorable. The location having been once established, it cannot now be changed, but a new point can be re-set in the same position and witnessed by a monument of sufficient size to be easily found. I have spent days at a time searching for a section corner which was my only reference, all trace of which had apparently vanished. After running lines from two or three different corners and looking carefully in the place where it should be, my quest at times was rewarded by the discovery of the point and its reference numerals, chiseled on the face of a rock not six inches square and flush with the surface of the ground, over which I had trampled a score of times. Probably I have failed to find one-quarter of the corners for which I have systematically searched. On some occasions, I have found the corner, usually a block of stone, loose on the surface of the ground with nothing to indicate its proper position, so that for a reference point the corner was worthless. These conditions obtain in all our Western States.

"A pine post 4 ft. long, 4 in. square, set 18 inches in the ground in a mound of stone", is the usual wording of a corner description in the survey notes of a mineral patent. It goes without saying that this means of identification will not last the life of the average mine, and what miner has not tested his corner-stakes to find that more often than otherwise a child could push them over if he were so inclined. In some localities, the timber in the posts will rot in six months time, so that the corner becomes useless, and, if near a road, a passing vehicle sometimes collides with the stake, giving it a helpless appearance, if not taking it out altogether. In contracting for a patent survey, which is the usual procedure, it is well to specify in the terms of the agreement that the posts must be charred or creosoted and set well in the ground in substantial blocks of concrete; and to see to it, by personal inspection, that the scheme is carried out. An even better way is to use a 4-in. pipe 6 ft. long, set 3½ ft. in concrete. The pipe is provided with a metal screw cap, on which is inscribed the survey number and usual markings of the patent corner. It should also be centre-punched, giving the exact position for the bob when a set-up is made over the corner.

Patented claim as well as section corners, should be kept in condition and not allowed to run down. Special inspection once a year would help matters, and, if corners were found in bad shape, the owner should be informed and made to bring them up to the standard. In nearly all controversies relative to patent notes, and the corresponding position of the claim corners, the courts have sustained the position of the monuments on the ground. An instance comes to mind of a case where a deputy mineral surveyor gave the course of his reference tie as northeast when it really was southwest, thus putting the claim in a different section from that in which it really was. The error was overlooked and the notes were accepted, followed by the granting of the patent. The reason for the preference given the monuments over the survey notes in a case of this kind is apparent. Again, there is a claim in the Bisbee district, Arizona, that is 1700 ft. long, the notes calling for 1500. The patent was issued before the error was discovered, and the posts stand as legal corners. Another case in the Ely district, Nevada: On a claim patented no later than 1906, the patent notes call for a 1200-ft. side-line, and all available records show this to be the correct distance, while the posts on the ground measure but 1000 ft. apart, and, therefore, fix the boundaries. In any case, and dozens of similar ones can be cited in every district, should all trace of the corners be lost, then all the data that are available to re-set the posts are the notes of the patent survey. Imagine, then, the tangle in the instance just cited, with a section tie over 8000 ft. long. It is plain to see that complications would arise that could be adjusted only by long and tedious litigation.

A practice which, I regret to say, has been often suspected, is that unscrupulous property holders adjoining valuable mineral claims will move the stakes of these to suit their convenience, and the change, perhaps, will not be noticed for some years; at which time there is nothing to prove the truth of the situation either one way or the other. If these unscrupulous persons have an understanding of the details of engineering and patent proceedings, they can so distort conditions that a re-setting of corners to anything like their original position is altogether out of the question.

There are few mining men, if any, who are not familiar with the red tape and tiresome delay connected with an application to secure a mineral patent. This is especially noticed in pioneer camps which have, perhaps, spent years in oblivion and later come again into active development. There are scores of old patented claims with most of their monuments gone and nothing but the notes to work from, which are usually much in error. As a result, the granting of a patent to adjacent ground will be, perhaps, indefinitely

withheld, as the notes of the new survey when plotted on the maps of the Surveyor General's office will possibly show an encroachment on the prior patent. This overlap probably does not exist in the field, but is due to an error in the field notes. A parallel case to the one just described has occurred in many districts, and it is only after various surveys, and awaiting the convenience of special agents to make investigation, that there is any hope in getting title to the property.

It would be a great advance if the Land Office would institute triangulation in every mining camp of importance, re-determine the correct position of all existing patent and section corners, and give to each post its proper latitude and longitude difference, or, as commonly called, its latitude and departure. Deputy mineral surveyors could then be instructed to lay out new patents from this system, and the standard of accuracy brought from the present allowable error of one in two thousand to something like one in twenty thousand. A fund of information would be accumulated that would be invaluable toward expediting the issue of patents, and the notes on record would then have an actual value. It is truly laughable to read on a patent plat the course of a line as bearing N. 45° 26′ 19″ E., and going in the field, to find that the bearing is incorrect by several degrees. With the arrangement as suggested, all deflections would be made from the same bearing, and there would seldom be any necessity for the tape in the field, the awkward end of which, no doubt, is responsible for many erroneous measurements. The deputy mineral surveyor in good faith, however, is required to make affidavit as to the accuracy of the survey to the best of his knowledge and belief. One great trouble in the present procedure is that there is little or no check on the field work, and the surveyor measuring a line in error calculates other courses and distances from this line, which when figured in a traverse, closes within the required limit. The error passes unnoticed. Particularly is this error noticeable in the section ties in a group of claims. Usually one is measured and all remaining ties calculated from this, so that in the event of an error in the first measurement the entire group is incorrectly located.

Take for example a dividing line between two valuable mining properties. The claim corners have been lost, and when the value of the ground has later been determined, a dispute arises as to the original position of the dividing line. The court decides that a deputy mineral surveyor under heavy bond shall umpire the dispute by re-running the old patent survey. After he finds what he thinks to be the proper section corner or mineral monument to which the claim was tied, he may run his lines with inclined sights and a long tape where the pioneer 'broke chain' and measured what he assumed to be horizontal distances. The engineer re-running the survey will establish the line, perhaps failing to check the old survey by an error of one foot in five hundred, and if the nearest reliable reference was a mile away, his point will be ten feet from the original position of the claim corner. The tendency in measuring distances by 'breaking chain' is to measure short, that is, the line instead of being 1500 ft. long might only be 1495, owing to the impossibility of holding the chain in a truly horizontal position. This difference does not help the desired result, but in the case under consideration one or the other of the companies, since they must abide by the decision, must move its line back 10 ft., making a present to the opposing company of a strip of ground 10 ft. wide and possibly 1500 ft. long. Should this area cover a depth of 300 ft. of 2% copper ore, it would mean a gift of $1,500,000. Should there be closer references and the error of resetting the line be only one foot, the loss still reaches $150,000. Since the work of establishing a triangulation system on a large mining property can be done at odd times, and the cost of instruments and materials is but little over $2000, its relative worth is apparent.

In the best scheme of triangulation there are two systems, a primary and a secondary. The primary embraces the stations on the most conspicuous points that are to the greatest degree intervisible and any combination of which will form well proportioned figures. In other words, the arrangement should be such that a station is determined by two lines intersecting as nearly as possible at right angles. These stations are lettered alphabetically. The secondary system is taken from the first, and embraces all stations of a secondary nature that must be set in less important places to obtain sight of a few minor points, and for which the degree of accuracy need not be so rigid. These stations are usually numbered. Figures 1 and 2 show the arrangement of a good type of station to be used. It consists of a triangular plate (A) ⅝ in. thick with a 3-ft. piece of 1¼-in. pipe (C) screwed in the centre and rigidly set. At each corner of the triangular base a hole (M), Fig. 2, is bored to accommodate ¾-in. bolts 18 in. long (B), Fig. 1, threaded for 6 in. on one end, and on which a nut (G) is placed both above and below the plate. The three bolts are then cemented in ⅞-in. holes, as shown in Fig. 1, spaced and drilled in the rock outcrop, if such be available or, if not, set in a substantial block of concrete. The plate with standing pipe is placed over the bolts and, by means of the nuts, is adjusted to a vertical position, which may be plumbed with an ordinary spirit-level. In cases where the engineer has reason to suspect that blasting or other work might injure or interfere with the station, a ¾-in. bolt, E, 18 in. long, split at the bottom with a steel wedge entered (see Fig. 1) is driven into a ⅞-in. hole, thus binding it firmly against the wall. This bolt is centred directly under the standing pipe of the station. The hole is then filled with liquid cement and the head centre-punched at the exact point, so that if the entire station above be carried away, the point will be left intact. When the base and pipe have been set and adjusted, a 10-ft. piece of 1-in. pipe (D) is placed in the other pipe, into which it telescopes easily and fits just tightly enough to insure adequate resistance against vibration from the wind. The pipe is marked in 1-ft. lengths beginning at the top and painted alternately red and white, as these colors can be seen best from a distance. This arrangement gives a permanent station, and, by removing the 10-ft. rod, a point over which a set-up can be quickly and accurately made by centring the bob in the pipe beneath.

Probably nothing in the entire scheme of triangulation requires the accuracy necessary in laying out the base lines, as the efficiency of the system depends on these measured distances. There should be two lines, one at either side of the property, if the area embraces 1000 acres or more, which should be laid out on as level ground as the country permits and should not be less than 3000 ft. in length. When the position of the base line has been determined, a station is established at each end and hubs driven along the line, carefully centred with small-headed nails, so that a tape may reach from one to the next without interference. Supports must then be erected at intervals of 25 ft. between the hubs to keep the tape in a truly straight line. The tape should be standardized for temperature and 'pull', so that when the line is measured, the corresponding corrections can be made, as without this the work cannot be checked closer than two-tenths of a foot in a line of this length. Precise levels are then run over the hubs, determining the exact elevation of each, the vertical angles calculated and the inclined distances reduced to the horizontal. Under no condition should the line be measured by reading the vertical angles from the instrument, as there is too great a latitude for error. Each line should be thus carefully measured at least six times, and the average taken. When the base lines have been adjusted to the satisfaction of the engineer in charge of the work, the primary stations are set on the various ridges and points of vantage from which a large area of the property can be seen, bearing in mind that the figures be kept as well proportioned as the irregularity of the surface will permit. Two lines making an angle of, say, 50° approach too nearly a parallel condition, making their intersection a much more difficult point to accurately determine than if they crossed at a wider angle. The system is now ready for the first checking.

The instrument best suited for this kind of work is any standard 5 or 10″ theodolite with which angles can be

checked to 5″ by repeating the reading several times, allowing the total angle turned to accumulate on the plate and dividing by the number of times it was read. Having decided on the instrument to be used, solar observations are made with this from each base line to determine its true azimuth, which, when convenient, should be checked by observations on Polaris. From the set-up at each end of the base line, backsighting the other end, the angles are turned as described, always to the right, on each of the stations visible from both ends, and the angles recorded. The process is repeated at the other end of the line, the transit moved to the next station, and so on until the base line at the other end of the property is in sight, and the angles to both ends read from all the stations possible. This will constitute the first set of field notes; the computations are then made, using the azimuth and length of the base line AB and carrying the calculations to the base line CD, which, when computed, should agree with the azimuth and distance originally determined by direct observation and measurement. If the work does not check, a re-measure-

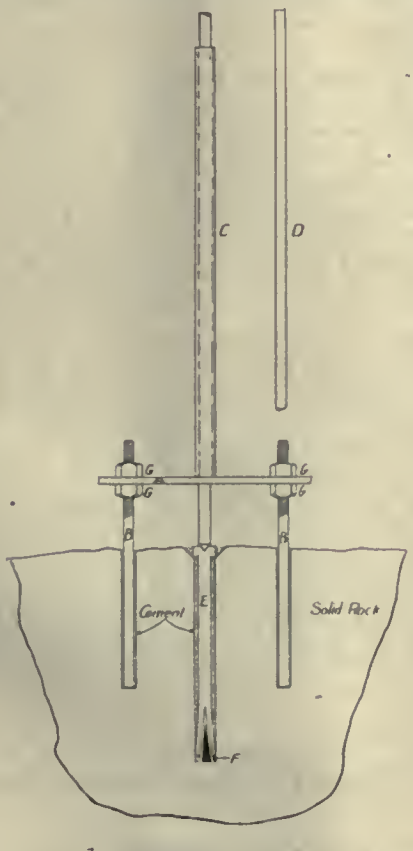

FIG. 1. TRIANGULATION STATION.

ment is necessary and new averages determined on both until the two agree to within a limit to be determined by the engineer, depending wholly on the accuracy of the instruments and the care with which the operations have been performed. Continual checking will be found necessary, lasting over a period of months, until the system is without errors. The stations of the secondary system are then located and set, as required. The fundamental operation is based on the trigonometric rule that in any triangle any two sides bear the same ratio as the sines of their opposite angles. We have the known base from which to start, and the angle from each end to the third point. By application of the above, the other two sides are determined. The operation is continued throughout the series.

In choosing a zero for the system of coördinates, it is always good practice to take a point well to the south and west of the property, so that the latitude and longitude differences for all points will be in the first quadrant—that is, will all be north and east of the zero and possess the same sign, plus. There is no necessity for establishing an actual station at the 00, as there is no occasion to use it. In case the mining companies of an entire district wish to use the same coördinates, which is very convenient and generally very much to be desired, the zero can just as well be in the next county. The reason for insisting on working in the first quadrant is the elimination of a possibility of error by carrying both plus and minus signs. It simplifies the calculations, as latitude and longitude differences are then added and subtracted directly, not algebraically. The lettering of coördinate lines is confusing and should be avoided. If a point is referred to by its coördinates, as for example, $\frac{106950.96}{108576.42}$ it has but one meaning, that is, 9650.96 ft. north and 8576.42 ft. east of the $\frac{100000}{100000}$ intersection. Before the system is used, all claim corners should be put in good condition, and given a

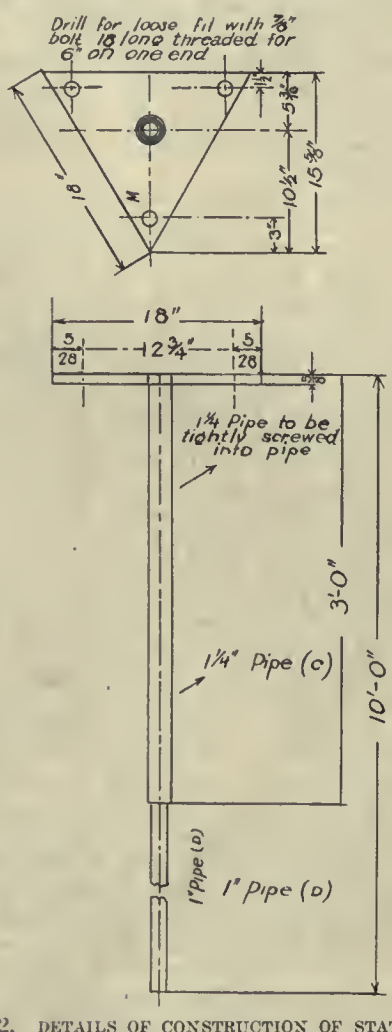

FIG. 2. DETAILS OF CONSTRUCTION OF STATION.

serial number from one up to as high a number as there are posts on the property. The next company can begin with the last number and continue, so that there is but one post with serial number 174, for example, in the district. Two theodolites are then set up on adjacent stations, and a rodman instructed to hold his rod on a post, at the same time showing the men at the instruments, by means of chalk and slate, the serial number of the corner. The point is read by each instrument, the angles repeated a few times to insure against a mistake in reading; the rodman then is signaled 'all right' and moves to the next corner. At no time should a post be read from stations making a triangle with an interior angle greater than 120° nor less than 30°. Our laws as to mineral patents are sadly in need of revision before the members of the mining profession can rely with any degree of certainty that there is absolutely no question as to the correct position of a corner and that there is available information on record that will positively re-determine the position of a post in the event of its removal. I hope these suggestions may be of some use to engineers meeting with similar difficulties, and if others have found the same hopeless conditions, that steps may be taken toward the setting and maintaining of a higher standard of accuracy.

Copper Production in Japan

By T. Haga

The copper production of Japan during 1910 amounted to 83,495,170 kin,* valued at 26,426,320 yen.† It is the principal mineral product of Japan, as its production is the largest, excepting coal which is 25% of the total mineral production. Compared with the previous year, the production shows an increase of 7,173,026 kin in quantity and 1,890,070 yen in value, or 7.7%. The reason for this increase is not the activity in the copper market, but the growth of the mines, as well as the opening of new ones. The Hidachi mine increased its production by 1,560,000 kin; the Ozarizawa, 950,000; the Furokura, 1,010,000; the Besshi, 590,000; the Kamaishi, 430,000; the Kunitomi, 400,000; the Ashio, 370,000 kin. On the contrary, the Kosaka mine showed a decrease of 360,000 kin; the Kano, 430,000; and the Ani, 340,000 kin.

Among the leading copper mines, those which produce over 2,000,000 kin each are the Ashio, owned by Furukawa Mining Co.; the Besshi, owned by Mr. Sumitomo; the Kosaka, owned by Mr. Fujita; the Hidachi, owned by Mr. Kuhara; the Ozarizawa and Furokura mines, owned by the Furukawa Mining Co.; and the Ikuno mine, owned by Mitsu Bishi Co.; they produced in 1910, 11,843,406, 11,132,371, 10,560,501, 8,059,013, 3,634,121, 2,302,595, and 2,259,154 kin respectively. Besides these, the ones which produce over 1,000,000 kin number 9, those which produce 500,000 to 1,000,000 kin are 11, and there are many small mines. The world's copper production for 1909 was 834,940 long tons, of which the output of the United States was 487,020 tons. The remainder, or 347,920 tons, was produced by Mexico and 21 other countries, of which Japan ranks fourth, with a production of 45,000 tons, or less than one-tenth of that of the United States. Nevertheless copper is the leading mineral export, 60,254,246 kin in quantity and 21,176,119 yen in value. The total of mineral exports for 1910 was 42,846,878 yen and imports 68,967,271 yen. The excess of imports over exports was 26,120,393 yen, due chiefly to the importation of steel and kerosene. It is a matter of regret that the exportation of copper and coal cannot counterbalance this. Though copper constitutes 50% of the mineral exports of Japan, yet last year the imports amounted to 538,443 yen in the form of bars, plates, wires, and tubes. But it is a favorable indication that, notwithstanding the demand for these articles yearly increases, there is a tendency for their importation to decrease.

In regard to the destinations of the exports, America, England, and Hongkong lead, and next come Germany, India, and France. Years ago, copper was exported principally to other parts of the Orient, but since 1906 this exportation has decreased, and at the same time the exports to Europe and America have increased. In 1910 the total exports to the Orient constituted 31% of the total, and on the other hand, the total to Europe and America reached 65%, as shown by the following table:

Country.	Quantity. Kin.	Value. Yen.
United States	14,981,023	5,877,576
England	12,740,102	4,444,571
Hongkong	12,447,042	3,791,476
Germany	5,241,109	1,749,703
India	4,580,865	1,614,399
France	4,260,241	1,609,781
China	1,054,978	379,720
Italy	971,194	318,568
Austria	634,119	209,175
Manchuria	186,266	67,405
Korea	97,058	35,842
Straits Settlement	87,610	27,511
Others	2,101,777	679,991
Total	59,383,384	20,805,718

*1 kin = 1⅓ lb.
†1 yen = 49.8c.

Since the Russo-Japanese war, the price of copper has risen, and in 1907 in London standard copper advanced to £107 0s. 8d. and electrolytic copper to over £116. During the reaction the market sagged until it reached £52. Since 1908 various copper mines have suspended or been abandoned until 2600 properties were removed from the producing list. Since then there has not been any notable rise in the market and the larger mines have decreased their cost of production. Both in England and America steps have been taken to regulate the production of copper, with the result that since October last the market has been begun to improve and the Japanese producers are becoming more hopeful.

In my opinion, the staple minerals, especially copper, in Japan are produced at a high cost when compared with Europe and America, not to speak of inferiority in resources, the utilization of machinery, and the application of science. For example, in Japan there are few mines which are great bonanzas like those of the United States. Though the Besshi, Kosaka, and Kune mines have comparatively large veins, yet they are not remarkable. It is true that Japan is now utilizing machinery and the applications of science, but these are still primitive. Only in labor cost is Japan better situated than the countries of Europe and America, but the constitution and character of the labor is inferior. The cost of prevention of damage from fume and mine-waters is high, and accordingly the total cost is greater than in the United States. It is said that in the United States costs range from 7 to 10c. per pound. This being the case, in spite of the business depression, America is not so greatly affected. In Japan apparently the only recourse is to decrease the cost of production.

In conclusion, attention must be drawn to the fact that Japan is encouraging the manufacturing of articles of copper. This is because the authorities are contriving to check the importation of copper wire, tubes, plates, and other articles. At present, the copper production in Europe and America is gradually increasing, and the copper output of Africa will be increased when the railway is completed. This is a question worth the attention of the producers of Japan. The Japanese, on the whole, are lacking in knowledge of mining. Public opinion is hostile to a speculative industry, such as mining. In consequence, the mining industry, in general, has been carried on by persons of no credit and capital. So, although there are many possible mines, they remain unexploited because of the lack of reliable investors.

The History of the Cyanide Process

By J. McCombie

Although the cyanide process was born in Glasgow, it was cradled, reared, and brought to an advanced stage of perfection at Karangahake, where it was in full operation for nearly a year before its adoption anywhere else. To the Crown Mines Co. belongs the credit for introducing this process, in a practical way, to the mining world, early in the year 1889, almost immediately after its development by J. S. McArthur and his colleagues, R. W. and W. Forrest. It was brought about in this way: Thomas Melville, an old Auckland resident, floated the Crown Mines Co. in Glasgow, and some of the ore which he took home for flotation purposes was treated by the embryo cyanide process with highly satisfactory results. Arrangements were then entered into with the McArthur-Forrest company to built a plant and treat Crown ore at the mine. Pursuant to certain conditions a staff of hands was sent direct to the mine from the experimental plant, Glasgow. The members were: John McConnell, manager; Frederick Smeaton, assayer; James Tegart, cyanider; William Dempster, engineer; and Peter McFarlane, carpenter.

I give the names of these men here because there is a strong disposition on the goldfields of the Auckland province to belittle the pioneers in every branch of the gold-mining industry, and to relegate such men to obscurity. Owing

chiefly to want of good accommodation for the transport of machinery, there was a long delay attendant upon the completion of the treatment plant at the Crown mine, and a small plant was erected in the Woodstock furnace-house, in consequence. This plant comprised one breaker, one Lamberton mill—dry-crushing—two vats, fitted with mechanical agitators, one stock solution vat, one sump vat, one filter-press, and four small barrel towers, for precipitation purposes.

Briefly, the process was fine grinding, agitation, filter-pressing, and precipitation on zinc shavings. The first parcel of ore dealt with was taken from the Maria vein in the Kenilworth mine, of which I was then part owner, and manager, and which is now included in the Talisman company's property. The plant was started early in the month of June 1889, and I have now before me a copy of the first treatment sheet:

VALUE OF ORE BEFORE TREATMENT.

Gold	£4 0s. 0d.	per ton.
Silver	£1 19s. 0d.	" "
Total value	£5 19s. 0d.	" "
Recovery, gold	89.2	per cent.
Recovery, silver	70.9	" "

The strength of solution used was 0.5%, and the consumption of cyanide was 4 lb. per ton of ore treated.

After a series of experiments with both wet and dry-crushing, dry-crushing in Lamberton mills was decided upon, and the ore was treated by upward percolation, with subsequent water washes, pulled through each charge by means of vacuum pumps. This simple process more than realized expectations in the case of the Crown ore, and it was generally adopted throughout the Dominion, where it remained in use in a good many mills for several years. As depth was attained in the mines the ore became more refractory, resulting in a high percentage of soluble sulphates being formed in the drying furnaces, or kilns, and the consumption of cyanide became a serious item in the cost treatment. Then mill after mill went in for wet-crushing, with dilute solution of cyanide in the mortar-boxes, and the first man to give the new departure a practical test, with 20 stamps, was H. H. Adams, at Waiorongamai. Except in the case of the Crown Mines the system was not continued, and the process gradually veered round to ordinary wet-crushing, amalgamation, concentration, and hydraulic classification, in the order named, followed by percolation for the sand, with agitation and decantation for the slime.

This brings the history of ore treatment by the cyanide process up to date, when decantation is being rapidly superseded by filter-pressing, and a good many New Zealand mills now hold a front rank position in the matter of ore treatment. It seems strange, however, after trying so many variations of the cyanide process, that all have found it necessary to return to the starting point, by adopting the system first introduced at Karangahake, in the year 1889, by the patentees. Today the tendency is in the direction of abolishing amalgamation and concentration, and in the mill of the future there will only be one system of treatment, which will be confined to the cyanide process throughout, regardless of the character of the ore, provided it is all ground to an impalpable paste and dealt with subsequently by agitation and filter-pressing.—*Auckland Herald.*

Hidden Creek Mines

The Granby Consolidated Mining & Power Co. secured an option on 75% of the stock of the Hidden Creek Copper Co. last year, at $400,000, paying $25,000 at the time the option was taken. At a meeting held in Boston, June 15, it was decided to carry out the terms of the option, and in accordance therewith an additional payment of $175,000 was made June 16. The final payment of $200,000 is to be made on December 15 of this year. M. K. Rodgers, of Seattle, and associates, who had developed the mine to a considerable extent, were the vendors. Since the date of the option the Granby company has performed a large amount of work on the property for the purpose of exploration and development, and some of its engineers have estimated 6,000,000 tons of ore developed that will average 2% copper, 30% iron, 35% sulphur, 28% silica, 9% lime, and 75c. to $1 per ton in gold and silver. The mine is situated in British Columbia, on Observatory inlet, about 100 miles north of Prince Rupert. The Granby company now has 80% of the Hidden Creek stock, 5% of it having been acquired by private purchase.

American Institute Meeting

The American Institute of Mining Engineers signalized its fortieth anniversary and its one hundredth meeting by convening at Glen Summit, in the heart of the anthracite region, where the little group of pioneers first met and formed the society. The three days technical session from June 6 to 9 was spent in visiting the plants of nearby mining and manufacturing companies during the day, while the evenings were devoted to discussion of papers and social gatherings. Some forty papers were presented and gave rise to interesting discussions.

Cuban iron ores were discussed in a number of papers that have already been printed and distributed. These included: 'The Iron Ore Deposits of the Moa District, Oriente Province, Island of Cubt,' by Jennings S. Cox, Jr.; 'Exploration of Cuban Iron Ore Deposits,' by Dwight E. Woodbridge; 'Characteristics and Origin of the Brown Iron Ores of Camaguey and Moa, Cuba,' by Willard L. Cumings and Benjamin L. Miller; 'Origin of the Iron Ores of Central and Northeastern Cuba,' by C. K. Leith and W. J. Mead; 'Occurrence, Origin, and Character of the Surficial Iron Ores of Camaguey and Oriente Provinces, Cuba,' by Arthur C. Spencer; 'The Mayari and Moa Iron Ore Deposits in Cuba,' by C. Willard Hayes. Collectively these papers form a symposium discussing many phases of the great iron ore deposits that have recently been upsetting all calculations of iron ore reserves. These papers exemplify the excellent work that the Institute is occasionally able to do in bringing together a number of articles on the same topic for discussion where a particularly well informed audience is available. Oil and gas were represented by the paper on 'The Caddo Oil and Gas Field, Louisiana,' by Walter E. Hooper, already published in the *Bulletin* of the Institute. This paper is a brief but particularly comprehensive account of the field near Shreveport which has attracted so much attention for the last two years. When arrangements now under way for piping gas through Arkansas and to St. Louis are completed, 125,000,000 cu. ft. per day will be utilized.

Anthracite coal mining naturally came in for considerable attention. The papers presented were: 'The Preparation of Anthracite,' by Paul Stirling; 'The Storage of Anthracite Coal,' by R. V. Norris; 'The Anthracite Board of Conciliation,' by Samuel D. Warriner; 'Chamber Pillars in Deep Anthracite Mines.' Anthracite mining is so special an industry that to metal miners these papers have only a general interest. Much useful data bearing on handling and storing material in general is embodied in the paper by Mr. Norris, and the problems of labor taken up by Mr. Warriner are of universal interest. The success of the Anthracite Board of Conciliation has been notable and the plan evolved in that district is worthy of careful study everywhere.

The iron industry and its development from 1871 to 1911 formed the topic of an interesting summary of forty years progress by John Birkinbine. The sintering of the fine iron ores in the Dwight & Lloyd machine was described by James Gayley, and J. J. Porter presented an admirable study of the quantitative relation between the various factors affecting fuel economy in the blast-furnace. The discussion of W. H. Emmons' paper on the effect of manganese on secondary enrichment was continued by several members; C. R. Keyes contributed a notable paper on the origin of certain bonanza silver ores, and R. E. Hore discussed the geology of the Cobalt district from recent studies.

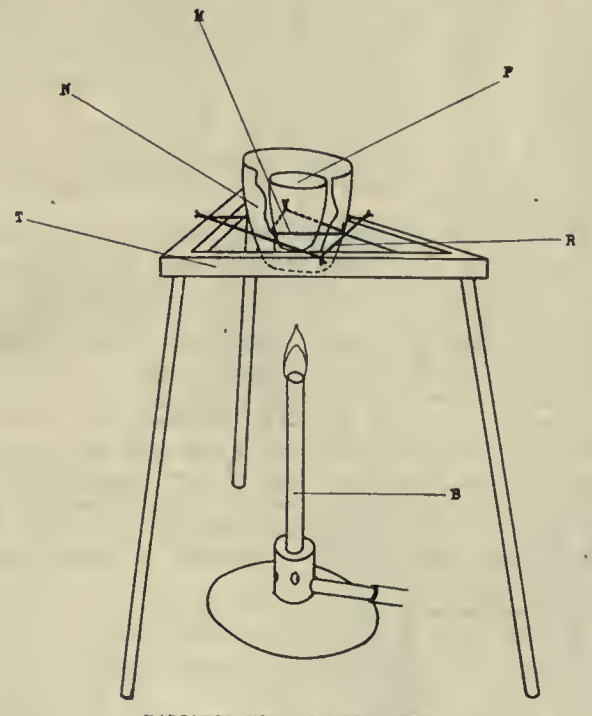
J. J. Brown described a method of smelting in the lead-

ore hearth which permits lowering of costs at the expense of slightly decreased initial extraction, and C. R. Keyes described methods employed in the assay of ores high in silver, while Edward Keller added to the discussion of the sampling of anode copper. The mining costs in certain of the mines at Park City were given in a valuable paper by F. T. Williams. Concentrating tables have of late years been the subject of much experiment, and S. A. Krom presented a description of a new diagonal-plane table which has many interesting features. The mining laws of the Dominion of Canada were the subject of a brief paper by J. M. Clark, to which the veteran Secretary added a discussion, together with a request for suggestions to Mr. Clark, who had been appointed by the Dominion Government to draft new mining laws. A detail of practical work was given by A. T. Schwennesen, who described the construction of a drafting table to be used in tracing through opaque paper. The meeting was greatly enjoyed by the members present, who highly commended the efforts made by the local committee for the entertainment of their guests.

A Radiator for Platinum Crucibles

By W. M. Thornton, Jr.

The accompanying drawing illustrates a very simple radiator for the evaporation of solutions to dryness in platinum crucibles. P is the platinum crucible, held in position by the Hoskins chemists' triangle M (a special nickel alloy). The ends of the Hoskins triangle are cut off at a point about midway their length and bent upward. The Hoskins triangle is supported by the walls of the nickel crucible N at a height that will hold the platinum crucible with its bottom and sides about equidistant from the bottom and sides of the nickel crucible. The outer crucible is supported by a triangle of nickel wire, R, which in turn rests upon a tripod, T, of iron (coated with aluminum paint). By placing a small flame under the outer crucible the inner crucible is uniformly heated by hot air, and its contents can be rapidly brought to dryness without danger of spattering. After the cessation of fumes the lid can be placed



RADIATOR FOR EVAPORATIONS.

on the nickel crucible and the platinum crucible baked at an even and moderately high temperature if desired. The apparatus in use by the author is constructed of a 'rein nickel' crucible of 100 c.c. capacity and a 1½-in. Hoskins triangle. These dimensions serve very well for platinum crucibles of 20 or 25 c.c. capacity. The following advantages are claimed for the apparatus:

1. It can be readily constructed of materials obtainable by any chemist at small cost.

2. Nickel serves as an excellent material for a radiator because of its high conducting and radiating power. It is also very resistant to burning and rusting; and, hence, is very durable. The Hoskins triangle is made of a very refractory alloy in which platinum vessels can be held and heated with impunity.

3. Since the shape of the 'rein nickel' crucible is approximately the same as that of the ordinary platinum crucible, all parts of the latter can be supported equidistant from the corresponding parts of the former, thus securing uniform heating.

The author has found the above form of radiator especially useful in the analysis of some highly titaniferous rocks from Nelson county, Virginia, in the laboratory of the Virginia Geological Survey. In separating the silica at 100° C. the titanium always hydrolyzes in large measure and precipitates on the separated silica. When the silica is subsequently determined by loss on evaporation with hydrofluoric and sulphuric acids, there is a considerable amount of solid titanium sulphate remaining. In conducting these evaporations on the hot plate, superheated steam and other vapors accumulated below a solid crust and much trouble was experienced on account of spattering. When the radiator was used, however, and with proper adjustment of the flame, spattering became a very rare occurrence.—*Journal of Industrial and Engineering Chemistry.*

Tin

Straits shipments for the first half of June were telegraphed on June 16 as 2300 tons, and for the whole month are estimated at 4700 tons. L. Vogelstein & Co. report that the tin available for June delivery—New York—promises to be about 3500 tons. As offerings of spot and June are limited, indicating small stocks, June deliveries will probably be in the neighborhood of 3000 tons—2000 tons less for the month and for the six months than last year. Assuming such to be the case, and allowing for the usual European deliveries and Straits shipments as above, the visible should about break even on June 30, that is, the same stocks will exist at the end of June as at the beginning, namely, 16,000 tons. This is the same quantity as was on hand June 30, 1910. In other words, it has come to this, that after a year of excited speculation based on predicted shortage, the market is exactly where it started, except in the matter of price.

An analysis of the situation shows small supplies in America as given, and probably also at other points, stocks having been attracted to London by the corner, and resting, presumably, in the hands of the syndicate. With the disappearance of the premium on spot, the market may be regarded as again in a normal condition except for this concentration of stocks, which, after all, is not an element of weakness in view of the good demand likely to follow. While prices are not low, tin is really in a stronger position than statistics indicate, owing to the exhaustion of invisible supplies. It is estimated that there are really 5000 tons less tin in the world now than a year ago. Buying to replenish stocks will doubtless exhibit itself with any further decline.

While the syndicate is generally supposed to have made money, its profits are as yet tied up in unsold stocks. How to harvest these profits is now the problem, a successful solution of which necessitates marketing holdings at a high price. Reference was previously made to the disastrous results following two preceding corners, but in regard to them it should be borne in mind that in one case the Secretan Syndicate failed, and in the other the panic in this country, the absolute suspension of business here, and our withdrawals of gold from all the world's markets, made a continuance of high prices impossible. Neither contingency threatens the present movement, and in view of the small supplies and good demand, much lower prices can hardly be looked for.

Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

IN coating steel or other furnaces, to render them fireproof, first brush over the brickwork to be covered with a solution made by boiling 1 pound each of silicate of soda and alum in 4 gallons of water, and follow immediately with this composition: Silica, 50 parts; plastic fire-clay, 10 parts; ball clay, 3 parts. Mix well.

ROPE may be rendered fire-proof by the following solution: Ammonium chloride (sal ammoniac), 15 parts, by weight; boracic acid, 6 parts; borax, 3; water, 100. The articles are to be left in the solution, heated to 212°F. for about three hours, then wrung out and dried. The mixture costs about 5 cents per quart.

VANADIUMISM is a disease which sometimes attacks workmen in plants where vanadium is used, especially in the trioxide form. The disease is marked by anemia, a dry irritating cough, and inflammation of the eyes and throat; it often results in tuberculosis. It is best prevented by protecting the workmen from dust by proper ventilation.

THE HOLDER of a bona fide mineral claim location within a forest reserve holds also the surface rights to his claim, and these are not subject to rental to others by the Forest Service. If he wishes to exclude stock from his claim he has the right to fence it in. Stockmen have no right to build fences across mineral claims, and the claim owner can not be excluded from access to his claim.

CORKS may be made impervious, and at the same time kept elastic, by saturating them with caoutchouc solution. Dissolve caoutchouc in benzine in the ratio of 1 part of the former to 19 parts of the latter. Into this liquid lay the corks to be impregnated and subject them to pressure of 150 to 180 pounds by means of a force pump, so that the liquid enters thoroughly. The corks thus treated must next be exposed to a strong draught of air until all trace of benzine has entirely evaporated and no more smell is noticeable.

ALUMINUM and other metals may be rendered unalterable and indestructible by water or atmospheric influences, by applying the following coating: Dissolve, preferably in an enameled vessel, 10 parts, by weight, of gum lac in 30 parts of liquid ammonia. Heat on the water bath for about one hour and cool. The metal to be covered with this varnish is carefully cleaned in potash, and, having applied the varnish, the article is placed in an oven, where it is heated, during a certain time, at a suitable temperature (about 1062°F.).

A VERY USEFUL and readily made support for doing hard soldering is composed of charcoal, asbestos, and plaster of paris. These are powdered in equal parts, made into a thick paste with water, and poured into a suitable mold. When this mass has dried it is removed from mold and a very thin cork plate is affixed on one surface by means of thin glue. The mission of this plate is to receive the points of the wire clamps with which the articles to be soldered are attached to the soldering block, the asbestos not affording sufficient hold for them.

A CEMENT which is effective for cementing rubber to iron and which is especially valuable for fastening rubber bands to band-saw wheels is made as follows: Powdered shellac, 1 part; strong ammonia, 10 parts. Put the shellac in the ammonia and set it away in a tightly closed jar for three or four weeks. By that time the mixture will become a perfectly liquid transparent mass, and is ready for use. When applied to rubber the ammonia softens it, but it quickly evaporates, leaving the rubber in the same condition as before. The shellac clings to the iron and thus forms a firm bond between the iron and the rubber.

IRON PIPES may be cheaply protected from rust by the use of enamel composed as follows: 130 parts powdered crystal glass, 20½ parts soda, 12 parts boracic acid. These substances, mixed in the most careful manner, are melted together in crucibles, the mass is chilled and transformed into a fine powder by crushing and grinding. The iron pipes are first cleaned in the usual manner by corroding, dried, and then coated with a very dilute gum arabic solution or any other gluing agent, and the powdered mass is spread over them by means of a sieve. The objects thus powdered are put in a room which is heated to 160°C. (to drive out all moisture) and are heated to dark redness, at which temperature the oxide coating melts.

GRINDSTONES are occasionally harder on one side than the other, causing the softer parts to wear away in hollows. This renders grinding difficult and soon makes the stone useless. The defect can be remedied completely by means of boiled linseed oil. When the stone is thoroughly dry, the soft side is turned uppermost, and brushed over with boiled oil, which sinks into the stone, until the latter is saturated. The operation takes about three to four hours in summer. As soon as the oil has dried, the stone may be damped, and used without any further delay. Unlike other similar remedies, this one does not prevent the stone from biting properly in the oiled parts, and the life of the stone is considerably lengthened, since it does not have to be dressed so often.

SULPHURIC ACID can be made from the SO_2 in the gases which escape from roasting and copper smelting plants, and this is now done in some cases. The two principal reasons that prevent its general adoption are, that, except in very large plants, the manufacture of a by-product, such as sulphuric acid, interferes with the regular work of the plant and is often a source of more annoyance than profit; and the escaping gases contain the SO_2 in too dilute a form to be readily utilized in the making of acid. If any considerable number of smelters engaged in the manufacture of acid the increase of the present production would be enormous, and it has been suggested to utilize it in the conversion of phosphates into fertilizers. By treating with the sulphuric acid the insoluble natural phosphate may be converted into a soluble or superphosphate which is a valuable source of phosphoric acid in agriculture.

ALUNITE is a hydrous sulphate of potash and aluminum. Attention of mining men was first attracted to it because of its accompanying the rich ore at Goldfield, Nevada. Taking this as a clue, R. T. Hill located claims near Las Vegas, and has carried on an active exploration for gold. It is understood that low-grade ore has been found, thus partly substantiating his theory, but as yet no rich ore has been uncovered. Lately the possible value of alunite as a source of potash has been discussed, and it has even been proposed to leach the Goldfield dumps. It is not impossible that this may prove to be important. Alunite contains 11.4% potash, and veins 6 to 10 ft. thick are reported from Sevier county, Utah. The mineral is hexagonal, occurring in rhombohedrons, and also massive with a fibrous to granular structure. It has a conchoidal to splintery fracture, vitreous lustre, and a hardness of 3.5 to 4, with a specific gravity of 2.58 to 2.72. It is white, grayish, or reddish, and has a white streak. It is infusible, but decrepitates before the blowpipe. Prospectors would do well to look out for the mineral. As the United States Geological Survey has a special appropriation for investigating potash minerals determinations can doubtless be obtained by sending specimens to the Director at Washington. Locate your claim first, however, so as to avoid conflict in case of withdrawal of the land. The material occurs in trachyte and allied rocks and is believed to represent alteration of rocks by sulphurous vapors. Make a lode location.

Discussion

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

Direct Solar Observation

The Editor:

Sir—The article on surveying by E. R. Rice, in your issue of April 22, as well as some previous articles on the same subject, is of much interest. Mr. Rice's treatment of the three-point problem reminds me that the United States Geological Survey has a blank for working out the problem that makes it very simple and rapid. I have borrowed the idea from the Survey of the direct observation of the sun. The accompanying form is one that I have been using for the past few months. With it I can work out a sun course in about half the time formerly required. These blanks also greatly help those who are not familiar with the problem. Of course the values for latitude given are only useful in this district and each surveyor will have to make out a set for himself, or look them up.

JAMES UNDERHILL.

FORM FOR SOLAR OBSERVATIONS.

Unavoidable Errors in Sampling

The Editor:

Sir—Referring to a letter from J. D. Whitney, which appeared in the *Mining and Scientific Press* of April 29, I believe that my article of this issue may be of value to him. I have indirectly shown that no two mines are alike, the most that may be said is that they may be similar, and no valuating engineer, if he knows his business, should attempt to group all mines in a general rule-of-thumb method in an examination.

However, I am looking at Mr. Whitney's trouble from a different viewpoint than is suggested in a previous paper by C. S. Herzig. It was there stated that, in many cases, a valuation computed in an office from submitted assay maps will give accurate and reliable results. In this respect I disagree, personal investigation and a method of sampling, depending on each individual case, is, in my opinion the crux and asset of a mine report, and I would congratulate myself if in an office examination I came within 25%, either way, of the results obtained from personally conducted sampling based upon a carefully considered program arranged to meet the individual case.

Not knowing the conditions, it is difficult to say under what class in the discussion in my paper Mr. Whitney's property would fall, but I refer him to class five, which may meet the case.

Investment in Prospects

The Editor:

Sir—Some friends have requested me to join with them in developing an orebody said to be 500 ft. wide, a mile long, and averaging $5.50 per ton in gold. Would it be wise to do this; and how should such a property be developed?

INVESTOR.

Chicago, June 14.

[Before expending funds for development our correspondent should take steps to ascertain what portion, if any, of his supposed orebody actually exists. When he has definite information as to the deposit any experienced engineer can advise him how to proceed. To save the cost of skilled advice is generally to be "penny wise and pound foolish."—EDITOR.]

Special Correspondence

BLACK HILLS, SOUTH DAKOTA

PROFITABLE YEAR FOR THE HOMESTAKE.—IMPERIAL AND TROJAN MILLS.—CASTLE CREEK DREDGE.—TEST ON ZINC ORE.—GOOD WORK AT WASP NO. 2.—FIRE PATROL CARS.—MICA PRODUCTION.

On June 1 the Homestake entered upon a new fiscal year, after closing one of the most productive years in its existence. During the past fiscal year the mine produced a little less than six million dollars in gold. Dividends to the amount of $1,330,400 were paid. The annual report of the company is distributed about the middle of August, and at that time all details will be available. The company suffered twice from fire within the past few days, the first outbreak destroying nearly $50,000 worth of hewed timbers near Rochford. This was nearly all 11-in. flat timber, ready for shipment to the mine. Indications are that the fire was of incendiary origin. Fire threatened to destroy the Old Abe hoist, but the Lead fire department saved the plant from what seemed sure destruction. A complete equipment for wireless telegraphy is being installed for the purpose of affording an independent line of communication between the main office at Lead and the hydro-electric power plant on the Spearfish, fifteen miles distant. This is the first installation of its kind made in the Black Hills.

The Imperial company is planning to start its wet-crushing cyanide plant in the First ward of Deadwood. The company's ore is now being shipped to the Lundberg, Dorr & Wilson cyanide plant at Terry. The work of driving from the bottom of the deep exploration shaft near the west side of the Imperial ground is about to be resumed. Operations were suspended a short time ago, following a fire which damaged station timbering and put the electric motor for the ventilating service out of commission. The fire was started by the motor burning out. The Trojan Mining Co. mill is about ready to start the first section of 150 tons daily capacity, and every effort is being made to have it in operation early in July. Drifts are being run to connect the mill with the mine workings, and gasoline locomotives will be used for hauling. All ore will be transported under cover—either underground or under snow-sheds. Among other improvements being made to the mill, Dorr classifiers and pulp thickeners are being installed.

The dredge of the Castle Creek Hydraulic Gold Mining Co. at Mystic, on Castle creek, was started in June. It is being operated by the Stearns-Roger Mfg. Co., of Denver, the builders, who contracted to erect and successfully operate the boat for thirty days. The hull is 102 ft. long and 30 ft. wide. The housing gives an additional width of 4 ft. The dredge will dig 35 ft. below water-line, the average extreme depth to bedrock being 34.6 ft. The bucket-line consists of 78 manganese steel-lipped buckets, each with a capacity of 5 cu. ft. As the bucket-line is geared to make a complete circuit in three minutes, 26 buckets will be discharged per minute. At a point convenient to the C. B. & Q. railway tracks, less than 200 yd. from the present location of the dredge, is the power-house, enclosing four 100-hp. boilers. Three of these will furnish ample steam to generate 250 kw. required for the operation of the boat, and the fourth will be held in reserve. A 300-hp. 28 by 48 Corliss engine drives the generator.

The Deadwood Lead & Zinc Co. has just completed the concentration of 15 tons of ore from the Dunn property, on Spruce gulch. The ore was taken to the Safe Investment mill, near Nemo. The product shows a good separation of the lead-iron middling from the galena, and the problem now is to secure a good separation of the zinc from the iron. Samples of the middling will be sent to plants equipped with Huff electrostatic machines, where a thorough test will be made. O. N. Brown, manager of the Deadwood company, is confident that a good separation of the zinc and iron can be made in the Huff machines, and, if so, Spruce gulch will be one of the biggest zinc mining camps in the United States, as the orebody is of enormous proportions, and hundreds of samples show it contains a fair percentage of zinc and lead, with a little gold and silver. The company has been financed by local capital entirely, and some of the shrewdest mining men in the Black Hills are heavily interested.

The Wasp No. 2 is again paying dividends. The new mill was started the first of last December, the former plant having been destroyed by fire several months previously. Since starting, the capacity of the plant has been gradually worked up to 490 tons per day, and will probably remain close to that figure. The production for May was $30,000, one-half of which was profit; mining, milling, and general expenses amounting to $1 per ton. The ore is mined in an open-cut, where it is shoveled into 4-ton skips that dump into bins at the top of the mill. The mill consists of a No. 5 Gates crusher, followed by two No. 1 crushers of similar pattern, and four 14 by 36 rolls. The ore is dry-crushed to 6 mesh, and given four to five days leaching in cyanide solution. The tailing is shoveled out through the bottom of the tanks and trammed to the dump. The low operating cost at this mine is record-breaking. The average bullion recovery lately has been around $2 per ton, this showing a saving of 75% of the assay value of the mill feed.

The district below Galena, and immediately adjacent to it, is a busy one, with building operations in progress in connection with the erection of plants and dwelling houses to be used in the working of the Osterman-Danckwardt smelter. All of the concrete retaining and foundation walls for both the smelter plant and the Gilt Edge-Maid concentration mill have been completed, and a large force of carpenters is now engaged in framing the timbers for the superstructure of these plants. In all there are about 60 men employed. The five dwelling houses being erected for H. C. Osterman, Paul Danckwardt, and employees of the company at a point a short distance up the creek from the smelter site are well along. There has been some delay in the work, owing to difficulty in getting prompt delivery of material, but on the whole the work is progressing satisfactorily and apparently there will be no trouble in getting the smelter going by the end of July. The work at the Gilt Edge mine, where N. Treweek, the superintendent, is opening a 96-ft. vertical vein of pyritic ore in the old King adit, is moving along smoothly, and undoubtedly the stopes will be opened and the mine in shape to produce a large tonnage by the time the smelter and concentrator are completed.

Lawrence county is doing commendable work in road building this year, the expenditure of the road fund at the present time being arranged to make more permanent roads and lessening grades. One of the most important pieces of work is the constructing of a new road up Dead Dog hill, between Deadwood and Portland. This will have a maximum grade of 8% when completed, thus cutting out one of the worst and most frequently used hills in the county.

The Black Hills section has been exceptionally dry this spring, the precipitation in June up to the 15th being 0.82 in. May was also unusually dry, and the result has been a number of forest fires. The C. B. & Q. railway runs for a hundred miles through the Hills, and its engines have started a large number of fires. This railway has now put on a number of fire patrol cars; a small car with gasoline motive power, which follows a short distance behind each train, and prevents many disastrous fires. The distance from a good oilfield, is, it is stated, all that deters the railroad from immediately equipping all its engines for using oil for fuel.

Mine No. 1, of the Westinghouse company, at Custer, is now being operated to full capacity, producing 4000 lb. of mica per week. The Westinghouse company is now securing practically all of its mica from its properties in the neighborhood of Custer, as this mica has been found to be of an excellent grade for electrical work. The Cuyahoga company is erecting a shaft-house and will sink

a shaft 100 ft. this summer. Lumber is being manufactured at the company's mill, on the property. F. A. Gira, of Custer, is superintendent.

TORONTO, CANADA

Diamonds in British Columbia.—Geological Investigations.—Closing of Iron Mines.—Railroad at Porcupine.—New York Attitude on Porcupine.—New Handbook.

The recent discovery of diamonds in British Columbia has been followed by another find of similar character in a locality distant about forty miles from Sherbrooke, Quebec. As in the former case the diamonds were found to occur with chromite, and to make the discovery commercially valuable some economical process for their extraction must be discovered. The Canadian Geological Survey has been for some time experimenting with this object in view. The perfecting of such a process would not only result in the establishment of a Canadian industry, but would give encouragement to chromite mining. R. A. A. Johnston, mineralogist of the Survey, will shortly leave for Germany to make further researches, taking with him a number of samples of the Canadian diamonds. The most important feature of the season's work of the Survey will be the commencement of the geological mapping of a second cross-section of the Rocky Mountains, following the route of the Canadian Pacific railway, which will be entrusted to a party of eight geologists in charge of R. A. Daly. It will probably require ten years to complete the undertaking. The services of another prominent American geologist, A. C. Lawson, have also been secured for the season for investigations in the Lake Superior region.

The Moose Mountain iron mines at Sellwood, 25 miles north of Sudbury, have been closed down for an indefinite period on account of the over-production of iron ore, throwing 250 men out of work. The company will proceed immediately with the erection of its new concentrating plant, to cost $300,000. The Canadian Government has issued an order in council abolishing the royalty on gold extracted from quartz in the Yukon Territory. This step was taken in order to encourage an industry, which so far has made such little progress that no royalty has yet been collected.

The laying of steel on the Porcupine branch of the Temiskaming & Northern Ontario railway has been completed, and the road will be in running order by July 1 as promised. It will be extended beyond Porcupine to the Pearl Lake district to serve the Hollinger and other mines, the Timmins-McMartin syndicate having agreed to finance the undertaking by loaning the railway commission about $150,000. Hydro-electric power from the Porcupine Power Co.'s plant on the Mattagami has reached the Hollinger, and the company will shortly be in a position to supply other mines. At the Hollinger over 200 ft. of driving has been done on the 200-ft. level; the vein is from 4 to 20 ft. in width. The assays are reported as being variable, but showing in some places high-grade ore of equal richness to that found on the upper level. The Rea is working on the 200-ft. level and the vein has been encountered in a cross-cut 14 ft. from the shaft, where it is considerably richer than on the surface. The main shaft of the Dome Extension is down to 75 ft. When the 100-ft. level is reached, a cross-cut will be run to intersect the vein 30 ft. distant. This is 36 ft. wide on the surface, with four lateral veins from one to three feet wide, running parallel, and all carrying good milling ore. At the Tisdale a new 9-ft. vein with good gold content has been found. The Vipond has cut, on the 1000-ft. level, the long high-grade ore-shoot that has been stripped for several hundred feet on the surface. It is claimed that it carries $40 per ton for a width of 3 ft. and $12 per ton for two feet on each side of the quartz. The shareholders of the Swastika have ratified a by-law increasing the capital from $1,000,000 to $2,000,000. M. W. Summerhayes has been appointed manager. C. W. Geddes succeeds Mowry Bates as manager of the Foley-O'Brien. W. L. Malcolmson, of London, recently visited the Porcupine camp in the interest of British investors. He was accompanied by H. B. Pearson.

Porcupine is carrying a good deal of dead weight in the New York mining share markets. Hostility to any market developments is plainly apparent. The press and the Stock Exchange maintain a distinctly antagonistic attitude. Nevertheless, most of the market activity is in the various Porcupine issues. The camp is evidently winning the endorsement of the best engineers who visit it, and enthusiastic friends of the new goldfield claim that all attempts to smother it will in the end make so many more friends for Porcupine. While several properties now stand as proved mines of size and merit, it is plain to see that owners are, for the most part, endeavoring to discount and capitalize the future and sell on that basis. There is a well conducted press agent's campaign in full swing on the Hollinger, evidently for market purposes. The Rea has been attracting much attention and is now looked upon as ranking with the Dome and the Hollinger. It has been stated that recently the Consolidated Gold Fields of South Africa saw fit to relinquish its holdings in this company. It develops that such is not the fact, and while the Consolidated Gold Fields holdings in the company are not held directly, it may be stated as a fact, that the Consolidated Gold Fields has never sold any of its stock.

Porcupine promoters and prospectors are waiting now for two things: the completion of the railroad, which is now into Golden City with construction trains, and the cessation of the black fly, which for the next three or four weeks makes life a burden for even the seasoned traveler through the bush and the muskeg. H. P. Davis has compiled a handbook of Porcupine, containing statistics and information, an accurate map, an outline of the geology, and a description of the important properties developed up to date.

JOHANNESBURG, TRANSVAAL

Tentative Geology on the Rand.—Unwise Exploration.—Details of March Production.—Decrease in Recovery and Increase in Working Cost.—Power Production by Mines.—Details of Cost.

For some time past the opinion has been expressed here that something should be done to obtain some reliable records of the training and fitness of engineers to report upon mines and properties, either by Government licence or otherwise. Here, as in other parts of the world, a far too liberal use of the letters M.E. and C.E., as mentioned in *The Mining Magazine*, is being made, and probably leads to misunderstandings; as it is not generally known that they only signify 'mining engineer' or 'civil engineer' as the case may be, and do not carry with them any certificate of training or ability to give competent advice in either branch of engineering. Even the local technical paper does not seem to use much discrimination in the selection of its sources of information, for in commenting upon some remarks sent previously, the local mining paper represents a map recently published in that journal with accompanying sections showing reefs in an impossible position, as a 'tentative geological map.' When a map shows the Government Reef overlying the generally accepted equivalent of the Main Reef Series, instead of underlying, as accepted by the Government Geological Survey, the word 'tentative' scarcely seems fit; especially as the author of the map also puts forward the heterodox view that the banket reefs of the Rand are of igneous origin. There has been a good deal of 'tentative geology' on the Rand of late; more especially during the last twelve months, and, strange as it may seem, nearly all the leading mining houses have been victimized by these tentative geological ideas into the spending of various sums in boring, and other exploration. These attempts to discover New Rands, and duplicates of the Main Reef Series, by the aid of local capital having resulted in complete failure, recourse is being had to London, and elsewhere, to obtain more capital for the purpose of continuing the search, and though the local attempts have failed, there seems every prospect of this additional outside capital

being obtained. One perhaps cannot blame the leading mining houses for spending money in prospecting where the stakes are so high, even though only 'tentative' geological views are advanced to support the theory. But when the views are proved by actual work to be wrong, it seems scarcely fair to ask people thousands of miles away to find further capital to expend on what is generally regarded here as a lost cause.

The Reef has not by any means obtained its highest output of gold, however heavy, and in some respects unwieldy, the large output has become. In April the average daily production was valued at £90,395, as compared with £88,962 in March, when the highest output of any previous month was obtained, so that it seems clear that only the shortness of the month prevented April showing another record output. There never was a time, perhaps, when the Rand had as much 'up its sleeve' in reserve as at present, both in developed ore and milling and reduction plants, awaiting labor and power to add their quota to the Rand gold output. Of the four hundred idle stamps at the Randfontein another hundred are soon to be dropped; and the City Deep is threatening to at least treble its output as soon as the necessary power can be obtained from the Victoria Falls Power Co. The Brakpan company, too, is on the point of entering the list of producers, while the Roodepoort United and the Bantjes can easily add to their output; not to mention the Meyer & Charleton mine, which will soon re-enter the list of producing mines with an enlarged shaft and rejuvenated reduction plant. The total gold output of the Transvaal for the month of April, as declared by the Chamber of Mines, was 667,714 oz. of fine gold, valued at £2,836,267; the total decrease as compared with March being 8351 oz., of a value of £35,473. The outside districts, it should be noticed, actually showed an increase over March of 2475 oz., valued at £10,511, so that the actual decrease on the Rand was 10,826 oz. The most noticeable features were the return of the East Rand Proprietary Mines to the top of the list; the falling of the Crown Mines from first to third position; and the improvement shown by the Nigel mine in the Heidelburg district. It has already been stated that an additional hundred stamps will soon be dropped at Randfontein, an event which, when they get into full swing, ought to place the Randfontein mine in the position of premier gold producer of the world, with two hundred stamps still in reserve. The April output was derived from these sources: Mills, £1,750,044; lands, £1,033,949; and miscellaneous sources, £52,274; total, £2,836,267. In April 1909, the total value of the output was £2,496,078, so that the increase cannot be said to have been at all startling or in keeping with the rapid and continued increases earlier made in these fields. But when we come to compare the profits made some time ago, we find the least encouragement; for in April 1909, with the output mentioned above, there was a daily average gold production of £83,200, and a daily average profit of £30,200; while two years later the average gold production has increased to £89,000, but the daily average profit has only increased to £30,600. The explanation for this will be found in the fact that two years ago the average yield per ton of ore crushed in the Rand was 29s. per ton, and the average working cost was 17s. 2d. per ton; but for March, the last month for which the figures are available, the total recovery per ton of rock milled was 27s. 7d., and the working costs 17s. 11d., so that the recovery per ton was 1s. 5d. less, while the cost of working was 9d. per ton more; a total difference of 2s. 2d. per ton, or half a pennyweight on the wrong side.

Notwithstanding the fact that the Rand goldfield is preeminently well placed, the mines being supplied by electric power from the Victoria Falls Power Co., several of the largest amalgamations, such as the East Rand Proprietary Mines and the Randfontein, have decided to generate their own power, and, where put into effect, the results have proved satisfactory. Take, for instance, the experience of the Randfontein Central property, consisting of five mines, over a length of four miles. These five mines produce about 184,000 tons per month, the maximum load expected for all purposes is estimated at 14,000 hp., while 19,000 hp. has been provided. The steam-plant consists of 24 Babcock & Wilcox land type of boiler, with a working pressure of 160 lb., fitted with mechanical stokers using dust coal, giving 11,500 B. t. u., costing 10s. 6d. per ton delivered into bunkers. The generating plant consists of two 1000-kw. sets, three 2000-kw. sets, and two 6000-kw. sets, all of them Parsons multiple reaction type. The capital cost of the whole installation was £312,000, or at the rate of £16 per kilowatt of plant installed. In March, 5,085,420 units were generated at a cost of 0.247d. per unit, the details of cost being as follows: Coal, 0.153d. per unit; repairs and maintenance, 0.046; salaries and wages, 0.038; oil, waste, and stores, 0.003; and office and general, 10,007; total cost of production being thus 0.247d. per unit.

LONDON

COAL MINES IN KENT.—NUMEROUS SEAMS DISCOVERED.—EFFECTS ON RAILWAYS.—HULTON EXPLOSION.—AN OVER-WORKED MANAGER.—SELLING CORNISH TIN BY METALLIC CONTENT.

Development of the coal deposits in Kent continues to be slow and, with the exception of that at Shakespeare Cliff, the pits have not yet reached the seams. The great hindrance to operations has been the large amount of water in the overlying chalk and greensand, and it has been necessary to provide an effective pumping plant to cope with it. The history of the exploitation of these deposits forms a chapter of romance in connection with English

CROWN MINES. SOUTH RAND SHAFT.

mining. It is seventy years since coal was found across the Channel, in France, and in 1852 the now celebrated collieries at Courrieres, and Lens started operations. Shortly afterward Godwin Austen, a land-owner in Sussex, undertook exploratory work in southeastern England to prove his theory that the same geological formation as in France would be found there. Murchison opposed the theory, but Prestwich was converted to it. Unfortunately none of the borings made by Godwin Austen or by Henry Willett ever struck any coal. The theory was revived in 1886 by Boyd Dawkins, of Manchester, who persuaded Sir Edward Watkin, then chairman of the South Eastern Railway, to continue sinking the shaft of the abandoned Channel Tunnel works at Shakespeare Cliff, Dover. In 1890 the boring cut the first coal seam at 1125 ft. Then followed a long period of financial and managerial entanglement. A split took place in the control, and Arthur Burr left, to conduct exploration work on his own account farther inland. He has since carried things forward by the sheer force of his own enthusiasm. Many bore-holes have been put down between Dover, Canterbury, and Sandwich, and many seams have been cut at depths of from 1400 to 2500 ft. The latest discovery is a seam 13 ft. thick. The borings have proved the existence of coal-land measuring 20 miles long by 10 miles wide. Colliery shafts have been sunk at Snowdown and Tilmanstone, but at neither place has the coal been reached so far, on account of delays due to scarcity

of capital and the necessity of providing pumping plant. The collieries are being well equipped. So far as can be ascertained the coal seams promise to be not more difficult to work than those in Scotland, but the problem of making a profit under the conditions ruling in Kent cannot be solved in advance. At present coal is expensive in Kent, as it has to be brought from South Wales or the North of England. The Kent railways have to pay high prices for their coal, and they are notorious for their inability to earn decent dividends or to improve their roads and rolling stock. With a cheap local supply of fuel operating costs would go down. However, it is only to be expected that when the Kent collieries start production, the coal producers that have hitherto controlled the market will cut rates, a policy which will be good for the community but not for the local collieries. The energy of Mr. Burr is extraordinary, and though a confirmed invalid, his enthusiasm is as great as ever.

Just before Christmas last a disastrous explosion occurred at one of the Hulton collieries in Lancashire. The Chief Inspector of Mines, R. A. S. Redmayne, has just issued a lengthy report on his investigations into the cause. The 'Yard' seam, in which the explosion took place, is notoriously gassy, and it has also the evil reputation of having an unsafe roof. Mr. Redmayne is of opinion that the explosion originated in a place where a gang of men were clearing a fall of roof, and he considers it probable that while they were doing so, there was another fall which liberated much gas. Then, either the sudden increase in gas overheated a lamp, or some of the falling material broke a lamp. It will thus be seen that carelessness took no part in the disaster, and that the stock story about a miner opening a lamp to light his pipe is found, as usual, to be unsubstantiated. But Mr. Redmayne animadverts on the want of skilled supervision, and considers that the owners are to blame for not giving Mr. Tonge, their manager, more assistance. Mr. Tonge is not only managing director of a company owning several collieries, but he is mining engineer to the company as well, and also manager of each individual colliery. This is too much work and responsibility for one man. Probably the company will take the hint and provide Mr. Tonge with the necessary skilled assistance. An interesting description by W. A. Halton, surgeon of the colliery, of the effects of the disaster, and the rescue work done there, appeared in *The British Medical Journal* for May 20.

The tin industry of Cornwall is being threatened with another set-back, owing to the metal merchants wanting to sell metallic tin by analysis. Unfortunately for Cornwall, the controllers of the metal market are more interested in the purer concentrate and metal produced from Malay and Australian gravels. The 'black tin' sold fortnightly at Redruth is by no means pure tin oxide, and the smelters pay poor prices accordingly. The metal people want to penalize metallic tin produced in Cornwall by £10 per ton for every ½% impurity. It is perfectly well known that Cornish metal is not quite so pure as that which comes from the Eastern gravels, and tin-plate makers would prefer not to buy it at the same price as Eastern tin. The Cornish smelters are up in arms and threaten to pay less to the mines, the eventual sufferers, unless the latter can pluck up courage and sell the concentrate in Germany, where much better prices can be obtained.

KETCHIKAN, ALASKA

Development Delayed for Want of Capital.—Too Optimistic Promoters.—Waste of Capital.—Some Promising Localities.

Very little prospecting has been carried on in this district during the last few years, principally owing to want of capital to develop the orebodies after having been discovered. It is to be regretted that in many cases the prospector has been holding his property at too high a figure, and asking a large sum for the initial payment, when the work done and the results hardly justify such a stiff price. Still there are a number of prospects of merit that can be had at reasonable figures. The favorable transportation facilities, numerous water-powers, mild seasons, and unlimited amount of timber everywhere should all tend to attract mining investors to this district. It is admitted by all who have examined this district that its greatest drawback has been the grass-root promoters, persons who have misrepresented facts to investors of limited means, claiming to have enough ore in sight to warrant the construction of tramways, bunkers, and other equipment necessary for shipping or treating the ore. The outcome has in nearly every instance been the same, when these improvements have been made, the funds are gone and the stockholder is still looking for returns; while if the same money had been spent in developing the orebodies, a number of mines could undoubtedly have been developed and funds could then be easily raised to furnish the mines with proper equipment for handling the ore.

At present two companies at least are doing first-class development work, and it has already been proved that the ore continues in depth and in some cases its value has increased slightly. The prospector in the near future will probably spend most of his time and energy prospecting for gold. The most promising localities in this district, so far as known, are in the vicinity of Dolomi, Hollis, Sea Level, Helm Bay, and a strip bordering on Tongas Narrows. A number of gold prospects at the places mentioned have more or less development work already done and are worthy of further investigation.

NEW YORK

Unwarranted Quotations.—Relative Earning Power of Shares.—Ohio Copper and Other Companies.—Lead Smelting Contracts.—Appraisal of Copper Properties.—Testing Permanence at Cobalt.—Progress at Porcupine.

Mining men, from prospectors to magnates, are perhaps more governed by sentiment than men in other walks of life, but that the power of such sentiment should prevail when mining securities reach the share market and should warp the attitude of the general public, seems improbable. Yet there are some market anomalies wholly inexplicable on any other hypothesis save that of sentiment. The copper metal market and the factors important therein have been analyzed and reanalyzed daily and weekly for months. During the month of May, domestic deliveries made a sharp increase. Stock piles have been low for months, and some consumers have replenished. The quotations on copper have advanced from 12 to 12⅝c., and there is much talk of further advance and improved prospects for the next quarter. While the bettered position of the metal is wholly legitimate, some of the alleged consequences can hardly be considered so. Amalgamated Copper has been moved from 61 to 70, a tremendous advance that cannot seriously be based upon the fractional advance in metal prices. Amalgamated pays $2 per year with no prospects of immediate increase, and sells at $70. Utah Copper pays $3 per year, with every probability of a largely increased output in the near future, yet it sells for $52. Nevada Consolidated pays $1.50 per annum and sells for $21.50. The Amalgamated could double its dividend rate, and still the present price would be too high. Nor is there anything in accumulated earnings or future prospects to justify the present market. Therefore, it must be sentiment. Issues such as Kerr Lake and Goldfield Consolidated are held down to less than 10% of the current price of Amalgamated, though disbursing the same amount in dividends. The man who sells Amalgamated and buys either of the two issues named, would multiply his present income by more than eleven times; as against the $2 he would receive something more than $22. The slight and recent improvement in copper is pointed to, but no account is taken of the new production to come from the investment of millions in the new low-grade milling properties: Ray Consolidated, 100,000,000 lb.; Inspiration, 50,000,000 lb.; Braden Copper, 37,000,000 lb.; Cerro de Pasco, 37,000,000 lb.; Miami, 28,000,000 lb.; an increase from Utah Copper of 65,000,000 lb.; with Chino, Mason Valley, and others not estimated. It is true that

the connection between Amalgamated and the International Smelting & Refining Co. has been strengthened by the purchase of the United Metals Selling Co., but the liabilities for the purchase of the latter, as well as for the purchase of the Butte copper properties of W. A. Clark, are still outstanding. Amalgamated has a surplus of $18,452,392, but this item alone cannot support the present price of the stock.

Chino is arranging its final financing by a bond issue of $2,500,000 of 6% ten-year gold bonds carrying the privilege of conversion into stock at $25 per share during any time within five years after twelve months from the date of issue.

The Calumet & Arizona has apparently benefited by the absorption of the Superior & Pittsburg. The shares have moved up some ten points, and it is taken as assured that the company can continue its present rate of $1 quarterly for some years to come. The Calumet & Arizona has paid to its shareholders just 100% on its present market price of $60.50.

At the recent meeting of the Ohio Copper Co. all the places on the board were filled by adherents of F. A. Heinze. It is now said that there will be a change of control, and that, as a matter of fact, all of the directors have signed resignations and that a new board can be placed in charge at any time. The Arizona Commercial and the Superior & Boston are to erect a smelter for the joint use of the two companies. A bond issue of $500,000 is said to have been underwritten for the Superior & Boston, and nearly all other preliminary negotiations have been completed. Ely Central is to be sold by the receiver to pay accumulated debts; the shareholders who bought shares at from $4 down will in all probability receive absolutely nothing.

The Hecla, of the Coeur d'Alene, and the Daly Judge of Park City, Utah, have each made a contract with the International Smelting & Refining Co. for the handling of their lead ores. The International management first planned a lead furnace to handle 250 tons per day. Now two furnaces are being constructed with a total capacity of 500 tons daily. The contract with the two companies named, the lead ores from the Utah Consolidated, and smaller lots of custom ores will provide enough ore to operate this part of the smelter at full capacity. The lead furnaces will be blown-in some time in October.

J. R. Finlay, formerly general manager of the Goldfield Consolidated, has been chosen by the Board of Assessors of the State of Michigan to examine 160 copper properties in the Lake country. Mr. Finlay in doing this work will, in a way, check over the results obtained by J. Parke Channing, who made the appraisals for the Calumet & Hecla merger. However, as Mr. Finlay is only allowed sixty days to make his returns to the State board, it follows that he can make little or no original and independent examination, but will be forced to simply compile the data gathered by his assistants. The work is in reality much too important to be handled in so short a time in a manner that is just either to the properties or to the examiners, who must be responsible for the reports made. Mr. Finlay has established headquarters in Houghton, and has a large corps of men already at work underground.

Fred Hellman, of Leggett & Hellman, has taken direct charge of the Wettlaufer property, South Lorrain, near Cobalt, Ontario. The Wettlaufer is a Lewisohn property, a subsidiary of the Silver Mines Exploration Co., and has recently been placed on a dividend basis of 5% quarterly. One of the very important undertakings in the mining world is that of the Nipissing Mines Co., which has just announced its intention to attempt to settle the much-mooted question of Cobalt ores at depth. On vein No. 64, which has already proved profitable to a depth of 245 ft., the company is to sink to 1000 ft. with cross-cuts at each 100-ft. level. Do the orebodies go down, has always been the query in Cobalt. The uncertainty has made Cobalt stocks the cheapest in the world in proportion to the dividends returned. Notwithstanding the fact that Cobalt was and is a poor man's camp, and has made such immense profits in proportion to the sums invested in equipment, the lack of proof of permanence has held back the share market.

The railroad from Kelso into Porcupine is so far completed that a regular passenger schedule is now being maintained. A large number of prospectors, investors, promoters, and brokers in New York are ready to go into the new camp, and a revival of local interest is expected. For the past six weeks the incipient Porcupine boom has been losing ground rather than otherwise in New York. There is no change of attitude on the part of the metropolitan press, and so far as the great dailies are concerned, the new mining camp is not on the map, but is obviously and studiously ignored.

BLUEFIELDS, NICARAGUA

CANCELLATION OF CONCESSIONS. — DEITRICK CONCESSION ABROGATED.—EFFECT ON DISTRICT.—SALE OF INTERESTS.

About the end of last March a government decree ordered that certain foreign concessions in Nicaragua should be considered by a mixed court, with a view to their abrogation. Now the president of the Republic has issued a decree declaring that the concession granted to James Deitrick, December 18, 1902, covering mines and mineral deposits in New Segovia and Jinotega, and that of December 6, 1907, to R. J. La Villebeuve, covering the mineral zones and abandoned mines of Bluefields and Prinzapulca, are abrogated. Three other concessions, covering steamship lines, the rubber industry, and harbor work were abrogated at the same time.

The concession granted to James Deitrick was subsequently acquired by the United States & Nicaragua Co. This company built a hotel and purchased steamers and barges, but did practically nothing toward developing the mineral resources of the concession, beyond taking in some

MAP OF NICARAGUA.

Hendy 3-stamp batteries, which were never erected. The company claimed that the mines in the Piz-Piz district were included within its concession, and as the Government refused to accept denouncements in the disputed area, development has been greatly hindered. Not long ago the mine-owners combined and, securing the services of a surveyor, made exact determinations of the latitude of the mines, with the result that none of them were found to be within the territory of the United States & Nicaragua Co. The abrogation of the concession will clear away any further chance for dispute. It is probable that this company will file a heavy claim for damages.

The 3700 shares of La Luz & Los Angeles M. Co., owned by A. Adler & Co. of New Orleans, have been sold to J. W. Fletcher of Pittsburg for $185,000. A. Adler & Co. still own 1100 of the 2000 shares in the Siempre Viva M. Co. and 301 of the 500 shares in the Topaz Mining Co. A description of the Piz-Piz district appeared in the *Mining and Scientific Press* for March 5, 1910.

General Mining News

ALASKA

The Innoko

Reports from Iditarod are to the effect that rich placer ground has been discovered in an old creek channel near Otter creek, by Charles Peterson and Elof Nelson.

Prince William Sound

A. K. Beatson developed the Bonanza mine, situated on Latouche island, at a cost of $105,000. He began operations in 1897, and later incorporated the Beatson Copper Co. to take over the property. In the course of development there was opened a big tonnage of ore that sampled 10% copper, and it was demonstrated that a profit of 4½ cents could be made on 9-cent copper at New York. The mine was sold two years ago to the Guggenheims, by whom it is being operated, with W. H. Seagrave as superintendent.

The Commonwealth Mining & Development Co. has been organized to take over and develop the lode claims located on Mineral creek, near Valdez, by H. Coggeshall, Robert Kernan, and Mrs. George Landon, who become stockholders in the company. The claims are close to the Williams-Gentzler group and are said to contain three veins in which fair-grade ore is found. The Ellis Imperial property has been equipped with an air-compressor, which is the first in use in Valdez district. William Thompson, Bert Ford, William Wilson, and Sam Blum, in developing their lode claims near Shoup bay, recently discovered ore, high-grade specimens of which assayed nearly $500 per ton. The ore occurs in a 3-ft. vein. The claims are in the vicinity of the claims of the Shoup-Glacier M. Co., on which ore has been found.

The Tanana

Rhoads & Hall, who have developed a quartz property on Bedrock creek, a tributary of Cleary, have purchased in San Francisco a Hendy 5-stamp mill, steam boiler, engine, and other equipment, all of which have been shipped to Fairbanks. Golden & Sherrard, mining near the head of Cleary creek, sent about 60 tons of ore to the Chena mill, the clean-up from which was gold bullion worth $5000. Much of the development of lode claims is in the vicinities of Cleary and Fairbanks creeks, which are from 18 to 20 miles out from the town of Fairbanks. The Tanana Valley railroad, which extends from Fairbanks to Goldstream and Cleary creek, was operated with difficulty during March on account of the heavy fall of snow, drifted by high winds.

ARIZONA

Cochise County

The production of blister copper at the Calumet & Arizona smelter, at Douglas, during the first five months of the year, was 9916 tons, which is 1163 tons less than for the corresponding period of 1910. The Shattuck mines of Bisbee have ceased operating, except with a small force on development work. The larger force of 125 miners was laid off.

The May output of copper at the Copper Queen smelter, Douglas, amounted to 9,543,779 lb. The ore from the Copper Queen mines, at Bisbee, yielded 5,719,187 lb.; ore and concentrate from Moctezuma mine and mill, at Nacozari, yielded 2,403,583 lb., while 1,421,009 lb. was produced from custom ore. The Detroit Copper Co., operating its mine and smelter at Morenci, produced for May 1,709,530 lb. copper. The Copper Queen mine and smelter, the Moctezuma mines, and the Detroit mines and smelter are all controlled by Phelps, Dodge & Co. of New York. It will be seen, then, that the total production of copper during May by these allied properties aggregating 11,253,309 pounds.

The Great Western Copper Co. expects to ship 1500 tons of ore from the dump at the Mame shaft in the Courtland district, to the El Paso smelter.

Gila County (Globe District)

The body of ore in the Inspiration group, near Miami, as demonstrated by development work and churn-drill exploration, is estimated at 24,000,000 tons. This deposit has a width of 1400 ft. in the widest place, and a length of 3500 ft. It is announced that the Inspiration Copper Co., which owns the property, is to proceed now with the designing and construction of a concentrating mill. The work is in charge of Henry Krumb, consulting engineer, and T. R. Drummond, the general superintendent.

Greenlee County

The production of copper by the Shannon Copper Co., Clifton, amounted to 1,220,000 lb. for May, and was 6,216,000 lb. for the first five months of 1911. It is claimed the Shannon is producing copper at a cost of 11¼c. per pound.

Some of the directors of the Arizona Copper Co. have been looking over the property of the company at Clifton, Metcalf, and Morenci, and the proposal to erect a new smelting plant probably will be decided at meetings soon to be held at Edinburgh, Scotland. It is reported that the company has acquired a site for the proposed smelter on the west side of San Francisco river, three miles downstream from the old plant.

Mohave County

The Cyclopic mines, in Union Basin district, which have been in charge of S. C. Bagg for two years, are reported sold to a company of Eastern people. The Union Basin M. Co., owner of the Golconda mine, is mining zinc sulphide ore, running 64% zinc, on the 400-ft. level. The company, according to the Kingman *Miner*, may be reorganized for the purpose of acquiring other properties in the vicinity of the original mine. The properties are in the Cerbat range, out 20 miles from Kingman, and are managed by John Boyle, Jr.

Yavapai County

The Climax M. Co. is developing its property, in the Bradshaw mountains, 18 miles from Prescott, and operating a small mill. A recent clean-up, made after a 5-days run, consisted of gold bullion worth $3500. There is said to be plenty of ore exposed in drifts and stopes, and it is probable that the mine will be worked on a larger scale.

The Cleopatra Copper Co., operating at Jerome, is shipping 500 tons of copper sulphide ore to the smelter of the Clara Consolidated company, at Swansea, in Yuma county. G. W. Hull and associates control the Cleopatra, and it is said they have 2000 tons more ready to ship.

Edward Block, of Prescott, has sold a group of claims in Copper Basin, on which there is a deposit of kaolin, 3 to 10 ft. wide, containing gold in profitable quantities. It is announced that the purchaser is to erect a milling plant.

CALIFORNIA

Oil Output for May

The gross production of oil for May of all the districts of the State was 7,099,449 bbl.; field consumption during the month, 394,190 bbl.; leaving a net production of 6,705,259 bbl., a daily net average of 216,300 bbl. The following table shows the net output in barrels by districts:

Districts.	May.	April.
Coalinga	1,542,292	1,382,770
Kern River	1,093,710	1,076,000
McKittrick	399,242	419,300
Midway	1,667,631	1,677,700
Maricopa	380,141	389,380
Whittier-Coyotes	94,151	93,941
Salt Lake	230,000	237,325
Fullerton	561,105	476,045
Ventura	32,553	37,601
Los Angeles City	36,800	36,500
Newhall	12,109	11,240
Santa Maria, Lompoc	650,000	699,916
Summerland	5,525	5,410
Total net production	6,705,259	6,544,128

Amador County

(Special Correspondence.)—The Alpine M. Co., operating at Plymouth, has cleaned out and partly retimbered the 600-ft. shaft, which is now in good condition from the collar to the lowest station. The company has leased for two months the Levaggi mill, which is to be operated for the purpose of making a number of tests on ore from the lowest workings. If the results of such tests warrant doing so, a 20-stamp mill will be built. F. Henry, the superintendent, is away for two months, and John L. Henry, the general manager, is in direct charge.

Plymouth, June 15.

The report of the Lincoln Con. M. Co., from March 15 to June 15, 1911, shows that the work on the 500-ft. level comprised the extension of the west cross-cut 442 ft. and the driving of the north drift 209 ft.; work on the 800-ft. level consisted in re-opening the old south drift and extending it 60 ft. in ore assaying $6.40 to $22.40 per ton. It is also noted that on the 1200-ft. level a west cross-cut is being driven in greenstone for the purpose of opening the vein that was reached on the 500-ft. level; this cross-cutting has been advanced 500 ft., and the vein is estimated to be 250 ft. ahead. During the quarter the company has expended $13,928 for labor, supplies, office expenses, fuel, freight, and power. The property is at Sutter Creek.

Kern County

The Butte mine, at Randsburg, is producing regularly under direction of Edward Shipsey, who is taking ore from the 50, 109, and 165-ft. levels. A 95-ft. raise has been driven from the 150-ft. drift on the 165-ft. level.

Mariposa County

The Oro Rico Mines Co., controlled by J. C. Wilson of San Francisco, and his associates, has had the Oro Rico mine under development during the last two years, and it is estimated that there is now 125,000 tons of ore blocked out, of an average value of $8 per ton. The ore consists principally of quartz, containing free gold, and sulphide material carrying silver, gold, and copper. The gold content represents about one-half of the value of the ore, the silver and copper the other half. The development comprises a 600-ft. cross-cut by which the vein is tapped at a depth of 320 ft., about 1000 ft. of drifts, and a 360-ft. winze, the latter having been sunk in ore on the main west drift. Stations No. 1, 2, 3, and 4 are established in the winze, and a level has been driven on the vein from each station; and in the stopes of this part of the mine is where the principal ore reserves are developed. The ore is raised to the main level by an electric hoist, set at the collar of the winze. The vein has a width of about 7 ft. The mine is situated in the vicinity of Coulterville, and is about 20 miles from the Yosemite Valley railroad. The 20-stamp mill, being built at the mine, is to be completed and ready to operate by August 25. It is being built by the Joshua Hendy Iron Works, and will have amalgamating plates and Deister tables. Electric power is supplied by the Pacific Gas & Electric Co. The Oro Rico was worked to some extent before this company acquired it. The holdings extend about two miles on the strike of the mineral zone, which is a part of the Mother Lode. The work is under the direction of Fred McMillan, consulting engineer.

The Original M. & M. Co., the stockholders in which are Merced people, recently shipped 23 tons of ore to the Selby smelter that sampled $62.60 gold and 53c. silver per ton, the gross proceeds being $1232; the net returns to the company amounted to $1091. The ore shipped was mined in the course of development, and was sent as a test. There is estimated to be 250 tons on the dump that will assay $40 to $50 per ton, and other shipments are to be made. This mine, known as the Original, is situated on the Merced river, close to El Portal, and is on the same lode as is the Hite Cove mine, which is on the line between Merced and Mariposa counties. G. W. Englehoff is in charge of the property.

Nevada County

The Gold Cañon mine and 5-stamp mill are now being operated by persons who have it under a bond. Development has been in progress since last fall. The water is being pumped out of the shaft to permit miners to work below the adit-level.

Plumas County

The Mother Lode Mining & Reduction Co. has built a crushing mill and cyanide plant of 150 tons capacity which is to be operated on tailing from the Crescent and Green Mountain mines, in Indian valley. The Dixie Queen mine, situated on Round lake, out from Johnsville, is now in operation, with W. T. Young in charge. G. McGee has commenced work for the season on the Salmon Lake mine.

Shasta County

The case of the Shasta county farmers against the Balaklala Con. Copper Co., relative to alleged injury to vegetation by smelter fume, came up June 20 in the United States Circuit Court, at San Francisco, and in accordance with a stipulation agreed to by attorneys for the litigants, an order was made by Judge Morrow to the effect that the defendant's smelter at Coram shall be closed down indefinitely before July 25, 1911, and that the company shall pay $4000 to plaintiffs to reimburse them for money spent in having analyses and investigations made. Between now and July 25 the company can smelt the 10,000 tons of ore stored at its plant. The stipulation also provides that the contempt cases pending against the company shall be dismissed.

The Big Seven Con. Gold M. Co., controlled by H. D. Staley and associates, is operating the Uncle Sam mine, on Squaw creek, 8 miles from Redding, with a force of 25 men. Three air-drills are in use in the mine. The 10-stamp mill has been in operation since February, crushing 20 tons of ore per day, the gold and silver being recovered on amalgamating plates and in the concentrate saved on the tables. It is claimed 90% of the assay value of the ore is extracted. This company does not own the Uncle Sam, but is working it under lease.

Sierra County

The Tightner mine, at Alleghany, owned by H. L. Johnson, by whom it has been worked during the last ten years, is under option to J. M. O'Brien of San Francisco, who has placed C. C. Derby and L. N. Wagner of the latter place in charge of the property. They are to explore, prospect, and sample the mine thoroughly during the term of the option. In order to facilitate such work Mr. O'Brien has purchased an air-compressor, power drills, electric motors, and other equipment, which were hauled from Nevada City to the mine last week and are being put in position for work. The air-compressor is to be driven by power transmitted to the mine from the plant of the Middle Yuba Hydro-Electric Power Co. The ore-shoot of the Tightner has been productive to a depth of 125 ft., and a long adit is being driven to tap this shoot at a depth of 600 feet.

The Monte Cristo gravel mines, near Downieville, are yielding gold at the rate of nearly $1000 per day. The channel is being worked to a width of 45 ft., and has been prospected and proved to a width of 60 ft. without reaching either rim. The Electric Separating Co., having a working bond on the Omega gravel mine, between Mountain House and Forest, has 28 men at work, mining gold-bearing gravel from the channel and running it through the mill. The coarse gold is saved by amalgamation and sluicing, the fine gold being recovered by electric separators. The gravel is cemented and requires crushing.

Tuolumne County

(Special Correspondence.)—Litigation over the Iron Spring mine has ended and the development of the property, which is owned by Ben Darmert and D. J. Sutton, will be resumed. About 25 men are employed in development work at the Tarantula mine, operated by the United Gold Mining & Milling Co. New hoisting equipment and self-dumping skip have been provided. The Wickham mine, near the Rawhide, owned by W. P. Houston and G. V. Snow, has been bonded to Bruce and Nelson, who will retimber the shaft and resume development. The crushing

plant at the Maddox mine, consisting of 5 stamps and a Huntington mill, was destroyed by fire. A new mill will be erected. The fire did not stop, however, the underground work, in which 12 men are engaged. The mine is owned and operated by the Phoenix Lake Mining Co. It is announced that the Santa Ysabel mine will be further developed. Six bars of gold, worth $16,000, the result of a clean-up at the New Albany mine, after a 20-day run, were sent to the mint this week. The property is owned by the United Mines Corporation, but for the last few weeks has been worked under direction of J. L. Gibbs, representing creditors to whom the mining company was indebted. It is understood that the gold taken out is sufficient to pay these claims.

Tuolumne, June 15.

COLORADO

Boulder County

The Colorado-Arizona Mines Co., owner of the Cash-Rebecca mine at Magnolia, has had a force of 12 to 15 men at work for 18 months, and during that time has built an electric-power plant, laid 4000 ft. of pipe for a water system, retimbered the mine shaft, and partly remodeled the mill and cyanide plant. Frank Leonard is in charge of the property.

Clear Creek County

(Special Correspondence.)—It is reported that the Centennial mine, on Leavenworth mountain, has been sold to New York investors for $125,000, by David Kennedy, the owner, who is in the East to close the deal. The Wide West mine, an old-time producer, has been taken under long-time lease by J. A. Noone. Operations were started last week and driving is in progress on a streak of carbonate ore assaying 475 oz. silver per ton.

Georgetown, June 17.

Lake County (Leadville)

The Yak tunnel, which cuts through the district from California gulch to the head of Big Evans gulch, is becoming a great factor in the development and extraction of ore. The Yak company is mining in Dollie B., Resurrection, Silver Cord, and White Cap ground, all tributary to this tunnel, and about 25 sets of lessees are working in properties along its course, many of them on mines in the vicinity of Big Evans. The ore sent out through this tunnel in the month of May amounted to 10,000 tons, which includes that shipped by lessees. It is claimed that $100,000 has been spent by lessees in developing ground tributary to this great haulage-way since the beginning of this year. Important work is being done on leased ground at the Resurrection and Sedalia mines. Included in this is the driving in progress from the Resurrection shaft No. 2, which is below the Yak level and is intended to tap the orebodies in the Diamond mine, supposed to contain sulphide ore of good grade. C. A. Edwards and associates, lessees on ground of the Seneca M. Co., using the Anderson shaft, have found a body of carbonate of zinc in a winze on the lowest level.

The Luema Mining Co. has sunk its Valley shaft to a depth of 600 ft. and has cut out stations at 500 and 600 ft., from which cross-cuts have been driven to the vein. It has been demonstrated by this work that the vein and ore are practically the same at 500 and 600-ft. depths as exists on the higher levels. The property is on South Evans gulch, and the Valley vein consists of a fissure in granite. This fissure has been opened for a length of 1800 ft. on the Cleveland group, lying to the south, and development in progress on the Silver Spoon group, to the north, is for the purpose of mining on the same fissure. The ore developed on the Cleveland runs high in gold, and is accompanied by some silver and copper of value.

The zinc ore being shipped from Leadville to Eastern smelters amounts to 500 tons per day. The number of zinc-producing mines is increasing in the district, and S. D. Nicholson, who has charge of the Wolftone, Henrietta, and Maid of Erin mines, is quoted as predicting a further increase in the production of zinc ores. The Little Pittsburg mine, being operated by H. M. Hoffer and associates, is again a producer of zinc carbonate ore.

Ouray County

The Grizzly Bear mining claims have been sold to the Gold Trio Mines Co., by which further development work is to be done. The Humboldt group of 16 patented claims, near Sneffels, belongs to John B. Farish and associates. The claims were located in 1879, and later were developed and made productive. Since 1893 the property has been idle. There is said to be ore on the dumps that could be handled now at a profit, and in the stopes and levels it is claimed there are 50,000 tons of ore that will sample $20 per ton. The mine is being examined and sampled by Fred G. Farish. It is on the trail which leads from Sneffels to Savage basin.

Summit County

The company which has driven the King Solomon cross-cut a distance of nearly 5000 ft., at Frisco, has shipped a carload of ore taken from No. 11 vein, intersected by the cross-cut, the smelter returns for which showed an average value of $36 per ton. This vein contains 2 ft. of ore, the principal metals in it being silver, lead, and copper. A narrow vein, close to No. 11, and parallel to it, has been opened, which is said to contain a streak of ore assaying about 18 oz. gold per ton.

The Wilson mine and mill, at Kokomo, are in operation under direction of H. M. Shepherd. The product of the mill is a concentrate. The Kokomo Metals Co. has built a mill which is ready to be operated. This company has developed in its mine a sufficient tonnage of lead-zinc ore to keep the mill supplied for some time. The property is on Elk mountain.

Teller County (Cripple Creek)

The 16 sets of lessees at work on the Isabella mines, Bull hill, are mining and shipping 10 to 12 cars of ore per week. The greater part of this is hoisted from the Lee shaft. A rich shoot of ore on the Buena Vista vein, at the 600-ft. level, is said to be 12 to 14 ft. wide, the ore being high grade. A carload of ore per day is being shipped from the Frank Caley lease on the Jerry Johnson group, Ironclad hill. Jack Gaffney and partners, sublessees on the same property, are now able to ship an occasional car of ore that runs $30 to $40 per ton. The Index Development & Leasing Co. is mining ore at the 500-ft. level of the Index mine, Gold hill, that samples about $35 per ton. Two carloads of ore were shipped recently.

IDAHO

Lemhi County

The Pittsburg-Idaho company, operator of the lead-silver mine at Gilmore, is shipping to Salt Lake City smelters 120 tons of ore daily. New steam boilers were recently put in place, and the company now has sufficient power to enable it to increase its force in development and production. The 400-ft. shaft, sunk from an adit, is being made deeper, and an inclined winze is being driven from the 400-ft. level to facilitate development work. Good ore has also been found in driving the Silver Dollar adit to the same vein 2000 ft. from the main workings. The ore in this mine occurs in short, thick shoots. Two parallel shoots, found on the 300-ft. level, were 200 ft. in length and 3 to 25 ft. in width, the ore sampling about 35% lead and 15 oz. silver per ton. These orebodies occur in a fissure in blue limestone. Gilmore is now reached by the Pittsburg & Gilmore railroad.

Shoshone County

The Coeur d'Alene North Fork M. & S. Co., which is operating in the Murray district, is mining ore regularly from stopes on the 800 and 1400-ft. levels, and concentrating about 200 tons of ore per day. The 1400-ft. level is that connected with the No. 3 cross-cut, driven 2300 ft. from Pritchard creek to the Monarch vein, cutting the latter at a depth of 1400 ft. These workings are connected with those above by an 800-ft. raise. The ores consist of sulphide of iron, containing lead and silver, with some zinc.

ILLINOIS

(Special Correspondence.)—The legislature, which has just adjourned, made the following annual appropriation for support of the State Geological Survey: Regular support, $25,000; survey and study of overflowed lands, $7500; preparing and engraving illustrations and maps, $2500; investigations of the coal mining industry and of coal waste with the Department of Mining at the University and the U. S. Bureau of Mines, $4500.

Springfield, June 12.

MICHIGAN

Houghton County

The May operations of the Wolverine Mining Co. may be summarized as follows: Ore hoisted, 36,168 tons; ore crushed, 34,944 tons; mineral recovered, 513 tons; yield of copper per ton of ore, 29.36 lb., which is an increase of about 2 lb. over the extraction made in April.

MONTANA

Lincoln County

(Special Correspondence.)—The churn-drill to be used in prospecting 400 acres of Libby creek placer ground, before deciding to build a dredge, has arrived, and the work is to be undertaken by T. Y. Ownby and G. F. Hinton, who represent Colorado and Eastern people. Tests will be made in order to estimate the value of the ground and determine its depth. The Silver Cable mine, owned by James T. Hartt, has been examined in the interest of persons who are figuring on acquiring the property. It is situated 23 miles south of Libby, and was considerably developed and equipped with a small mill a few years ago. It is said to have a 4-ft. vein of silver-lead ore.

Libby, June 15.

Silverbow County

The Original mine, one of the former Clark properties, is being developed by the Anaconda company. The 2400-ft. shaft is to be sunk to a depth of 2800 ft. The Tuolumne company has opened a body of good ore on the 1400-ft. level. When the south vein on the 1600-ft. level was reached, there was found a body of ore running from 5 to 12% copper. But it was discovered that the miners were in the High Ore mine, and in order to prove the ground, the Tuolumne people started to raise to the 1400-ft. level and cut the south vein. Where it was opened was 170 ft. nearer the shaft than on the 1600-ft. level, proving that they were in their own ground. Now, in order to further explore the ground, the company is raising to the 1200-ft. level.

NEVADA

Esmeralda County

The explosion of a charge of powder in a missed hole while miners were drilling in the Valcalde tunnel of the Pittsburg-Silver Peak mines, near Blair, on June 15, resulted in the instant death of Joe Busto, and the serious injury of C. Gasparovich, Walter Ward, and Robert Peterson.

Eureka County

The Eureka & Palisade railroad, sold last winter at foreclosure sale to Geo. W. Heintz of the United States S. R. & M. Co., has been redeemed by George Whittell, of San Francisco, one of the stockholders, who is reported to have stated that the washed-out sections of the road would be rebuilt. This work will require the grading and building of about 10 miles of road.

Lincoln County

The Mendha-Nevada M. Co., having a developed mine at Pioche, has shipped about 6000 tons of ore to the Salt Lake valley smelters, that sampled $30 per ton, and is now making plans for a mill to be built this summer. A lot of 11 tons of Mendha ore was concentrated at the ratio of a little over 3 tons to 1 by the General Engineering Co., Salt Lake City, the resulting concentrate assaying 0.59 oz. gold and 25.8 oz. silver per ton, and 34% lead, 12% iron, and 23% silica. The result of cyanide tests made on the vanner tailing showed that this material was amenable to cyanidation, that the consumption of cyanide was 1.8 lb. per ton of pulp, and that 18 hours agitation was sufficient in practice. The cyanide test showed the extraction of gold was 41.8%, and that of silver 14.8% of the content of the head sample. The concentration test showed a recovery of $10.35 per ton of crude ore, and the saving of $14.58 per ton by concentration and cyanidation.

Lyon County

The Nevada Douglas Copper Co., for which Duncan MacVichie is consulting engineer, is having its mines in Yerington district put in such condition as will make it practicable to mine a large tonnage of ore in an economical manner. The mine work is in direct charge of A. A. Arentz, whose development in the southern part of the Ludwig group has resulted in exposing bodies of ore of smelting grade not hitherto included in the ore reserves. This ore runs 6 to 9% copper. The second, third, fourth, fifth, and sixth stations of the Ludwig shaft are in good order and ready for active mining.

Nye County

The Tonopah Extension M. Co. mined and treated 4100 tons of ore during May, extracted 93% of its gold and silver content, the output for the month being 3835½ lb. of bullion, valued at $42,000. The mill work at this property was well described by John G. Kirchen in an article published in the *Mining and Scientific Press* of April 9, 1910.

The Round Mountain M. Co. is building a new mill which is expected to be finished in July. Meanwhile, the old mill is operating and turning out $30,000 to $40,000 per month in bullion.

Storey County (Virginia City)

The north drift No. 3, on the 2400-ft. level of the Mexican mine has been driven to the south line of the Union Con. mine, the face of the drift being in ore that assays $11.35 per ton. It is stated that the north drift on the 2500-ft. level is being advanced in ore toward the Union Con. ground, which is to be developed through those two levels on the Mexican. Ore hoisted from the Mexican for the week ended June 17 amounted to 375 mine-cars, of the value of $21,194. Of this, 63 cars, averaging $66.62 per ton, were taken from the 2300-ft. level; 78 cars running $5, and 74 cars at $27.08 per ton came from the 2400-ft. level; 39 cars, assaying $107.61, 106 cars running $92.60, 15 cars at $39.40 were taken from the 2500-ft. level.

The week's output at the Ophir was 275 mine-cars of ore, estimated at 248 tons, of an average value of $45.74; this was taken from the Hardy vein, on the 2100-ft. level. The work at the Con. Virginia consisted in driving on the 2550-ft. level, timbering on the 2450, and repairing on the 1750. No stoping was done.

Ward shaft work consisted in building the concrete bulkhead in the Gold hill drainage-level at 2000 ft., not yet completed; doing diamond-drill prospecting on the 2450-ft. level, and driving at the 2000-ft. level toward Julia ground. The Yellow Jacket mill was operated on dump ore. During the week ended June 17 the Mexican shipped 4 cars of first-grade ore to the smelter; the Ophir shipped one car of concentrate to the smelter, and 340 tons of ore to the Kinkead mill.

NEW MEXICO

Grant County

The stockholders of the Chino Copper Co. are to meet June 30 to act upon the proposal of the directors to issue bonds in the amount of $2,500,000. If this bond issue shall be authorized, all stockholders of record June 20 are to be entitled to subscribe *pro rata* on the basis of one bond of $500 for each 140 shares held. It is announced by Charles M. MacNeill, president of the company, that development work at the mines has resulted in such an increase of available ore as to warrant the increase in the capacity of the concentrator, now under construction, from 3000 to 5000 tons per day.

Socorro County

(Special Correspondence.)—The ore mined and milled at

the Socorro during May was 5000 tons. The output for the first 10 days of June averaged 155 tons per day, 93% of the gold and silver therein being extracted at the mill. The Ernestine M. Co. treated 3300 tons in May, from which was extracted 24,785 oz. of silver and gold, and 20 tons of concentrate. The property is now producing about 700 tons of ore per week, which is milled. The plant at the Deadwood mines is being increased. At present 250 tons of ore per week is being treated.

Alma, June 15.

OREGON

Baker County

The Underwood placer mine, situated on Boulder creek, two miles from Cornucopia, is being worked this season by J. H. Underwood and C. H. Rhodes, a clean-up made recently having amounted to $8000.

Jackson County

The Homestake mine, near Woodville, is to be operated by Captain Clark and associates, who have a lease and bond on it. They are overhauling the mill and putting the mine in condition for work.

Josephine County

The Michigan mine, situated on Applegate river, near Murphy, and 8 miles south of Grants Pass, is controlled by people resident of Charlotte, Michigan. It is in charge of Adolph Maier, who is erecting a mill of 25 tons daily capacity. The ore, according to sampling and assaying, runs $11 to $22 per ton. The vein is said to be in granodiorite, strikes southeast, dips 15° northwest, and has a width of 6 ft., the pay-streak being 2 to 4 ft. wide. There is one 2-compartment shaft, 135 ft. deep, with two crosscuts driven to the vein. Other development is near the surface.

UTAH

Beaver County

(Special Correspondence.)—The management of South Utah claims that the mine is producing 500,000 to 600,000 lb. of copper per month at a cost of 9 cents per pound, now that improvements have been made at the concentrator and the grade of ore has improved. The property is at Newhouse.

Milford, June 17.

Grand County

(Special Correspondence.)—C. D. Inman, of Goldfield, Nev., Frank M. Meyers of Seattle, and W. G. Page of Los Angeles have closed a deal for the purchase of 500 acres of placer ground which they say contains 12,000,000 to 15,000,000 yards of gold sands, estimated to run about 20 cents. The property lies in the La Sal mountains. Operations will begin at once.

Moab, June 1.

Juab County

(Special Correspondence.)—The Uncle Sam M. Co. has declared a dividend of $25,000, making a total of $445,000 paid since organization. The annual report for the year ended June 1, 1911, showed net profits for that year of $120,515, and cash on hand amounting to $62,751. The directors and officers were re-elected at the annual meeting. The Centennial-Eureka company has paid its first dividend this year, amounting to $3 per share, or $300,000. This makes a total of $30 per share, or $3,000,000 in five years. The United States Smelting, Refining & Mining Co. owns 98,864 shares out of the 100,000 shares of the stock. Iron Blossom, for the week ended June 10, shipped 38 cars of ore; the Centennial-Eureka shipped 36 cars. The Opohongo is sinking its shaft in copper-gold-silver ore, assaying close to $50 per ton. William Hatfield thinks he has the extension of the Mammoth vein.

Eureka, June 17.

Salt Lake County

(Special Correspondence.)—After a stockholders' struggle, lasting several years, control of the Columbus Consolidated at Alta has passed from the faction headed by Tony Jacobson, to A. H. Cowie, W. O. Williams, and C. H. Gibbs, directors, who will continue work of unwatering the lower levels.

Alta, June 17.

Summit County

(Special Correspondence.)—A raise of 1100 ft., from the Alliance adit, the 1500-ft. level of the Silver King Coalition mine, to the workings of the Keith-Kearns mine, has been completed after a year's work. The work was difficult on account of bad ground, and predictions had been made that it could not be accomplished. The Snake Creek adit was in 3472 ft. June 2.

Park City, June 17.

WASHINGTON

Stevens County

The Pacific Copper M. & M. Co., controlled by M. E. and M. S. Hosea, of Spokane, is reported having interseeted a 40-ft. lode of copper, gold, and silver ore, assaying over $30 per ton. Considerable amount of development has been done, a carload of sorted ore is to be shipped, a shaft is being sunk on the orebody, and a mill may be built later.

CANADA

British Columbia

It is stated that Frank C. Armstrong, of New York, and D. L. McGibbon, of Montreal, have acquired a controlling interest in the Sheep Creek Summit Gold Mines, Ltd., owner of the Summit mine, in Sheep Creek district, situated near Ymir. George E. Farish is to take charge of the work. Ore has been shipped during the last two seasons.

Ontario

P. Kirkegaard, consulting engineer for the North Dome Mining Co., at Porcupine, reports as follows under date of June 15: North Dome shaft down 34 ft.; sample taken at 32 ft., vein 7 ft. wide, ore assayed $84 per ton. Drill-hole 120 ft. deep. Expect to reach orebody at about 175 ft. Drilling is at the rate of 20 ft. per 24 hours.

MEXICO

Sonora

(Special Correspondence.)—The Barranca mine is closed down and has been left in charge of a watchman. The ore treated at the mill, built last year, proved disappointing, both as to the value and the extraction obtained. It is reported that checks given by the management on the Bank of Sonora for labor were returned marked 'no funds.' The Barranca, which has had a varied career, was partly developed by San Francisco capitalists, who sold it under a working bond to Stephen W. Dorsey, of Los Angeles, and he disposed of it in 1906 to the Hudsons Consolidated, an English company, which placed the property on the London market with a capitalization of £160,000, the latest quotation being 7 shillings 16 pence.

At the Berlin mine a hoisting plant is being provided and the workings are being unwatered, under direction of B. F. Ogden, acting for S. W. Dorsey, of Los Angeles. The Las Cruzas mine, situated near Snaqui Grande, and belonging to the Flores family, has been bonded to Mr. Fletcher, of Los Angeles, who is having the old workings unwatered. The property is one of the *antiguas* of the district, on which further exploration and development are to be carried on. Las Animas mine, at San Javier, has been bonded to Mr. Laughlin, who is overhauling the mill, with the intention of concentrating the ore and shipping the product to the El Paso smelter. The ore is low grade, carrying lead and zinc, and is considered difficult to treat. Those formerly in charge were unable to make a satisfactory product, much of the valuable metal being carried away in the slime.

Barranca, June 12.

Two smelters will soon be blown-in which are situated in the northern portion of Sonora, those of the Cobriza Mining Co. at Noria, and that of the Sonora Copper Smelting Co. in the same neighborhood. The two plants were completed some time ago, but on account of unsettled conditions the blowing-in was postponed.

Recent Publications

U. S. Bureau of Mines, Bull. 5, 'Washing and Coking Tests of Coal at Fuel-Testing Plant, Denver, Colorado, July 1, 1908, to June 30, 1909.' By A. W. Belden, G. R. Delamater, J. W. Groves, and K. M. Way; 1910; 62 pages.

The following publications have been recently issued by the U. S. Geological Survey:

Mineral Resources, 1909: 'The Production of Gold and Silver in 1909,' by H. D. McCaskey; 1911, 33 pp. 'The Production of Natural Gas in 1909,' by B. Hill; 1911; 136 pp. 'The Production of Asbestos in 1910,' by J. S. Diller; 1911; 13 pp. 'The Production of Asphalt, Related Bitumens, and Bituminous Rock in 1909,' by David T. Day; 1911; 5 pp. 'The Stone Industry and the Manufacture of Lime in 1909,' by Ernest F. Catalogues Received

Thos. H. Dallett Co., Philadelphia, Pa. Bulletins No. 203 and 204. 'Air Compressors.' 6 by 9 inches.

Robert W. Hunt & Co., New York. Outlining the field of operation of this engineering firm. 32 pages. 3½ by 6¼ inches.

The Bristol Co., Waterbury, Conn. Bulletin No. 131. 'Bristol's Recording Voltmeters.' 44 pages. Illustrated. 8 by 10½ inches.

Sullivan Machinery Co., Chicago. Bulletin 58-J. 'Sullivan Straight-Line Air Compressors.' 20 pages. Illustrated. 6 by 9 inches.

The Westinghouse Machine Co., East Pittsburg, Pa. Circular W. M. 503. 'Westinghouse Gas Producers.' 32 pages. Illustrated. 7 by 10 inches.

Edgar Allen American Manganese Steel Co., Chicago. 'Manganese Steel Castings.' Enumerating list of castings manufactured by them from manganese steel. 16 pages. 4 by 6½ inches.

Wm. Powell Co., Cincinnati, Ohio. Catalogue No. 10. 'Dependable Engineering Specialties.' Describing the 'Star' steam specialties. Useful tables, etc. 300 pages. Illustrated. 5½ by 8 inches.

Oliver Continuous Filter Co., San Francisco. Describing the Oliver Continuous Filter, with filter costs and metallurgical data of filter operations; also, list of installations. 16 pages. Illustrated. 6 by 9½ inches.

Thew Automatic Shovel Co., Lorain, Ohio. Catalogue No. 8. 'Thew Steam and Electric Shovels.' Describing their Full Circle Swing Shovel, mounted on traction wheels or car wheels; also for underground mining, ditch construction, and quarry service. 32 pages. Illustrated. 9 by 6¼ inches.

Decisions Relating to Mining

Specially reported for the Mining and Scientific Press.

Injury to Miner—Recovery

Three thousand two hundred dollars recovered for an injury to a miner whose hand was broken and who was permanently crippled by the falling of a lump of coal is not so excessive as to indicate either passion or prejudice on the part of the jury in assessing the damages.

Poli *v.* Numa Block Coal Co., (Iowa) 127 Northwestern, 1105. Oct. 1910.

Liability of Mine Operator for Negligence of Engineer

The fact that the operator of a mine is required by statute to employ only licensed engineers and pit bosses, does not make such engineers and bosses quasi-officers of the State to relieve the owner or operator from liability for negligence.

Poli *v.* Numa Block Coal Co., (Iowa) 127 Northwestern, 1105. Oct. 1910.

Bona Fide Purchaser of Mining Stock

A wife who receives mining stock from her husband in payment of or as security for a preëxisting debt, is not an innocent purchaser, and takes such stock subject to the lien of the corporation for the indebtedness of the husband to the corporation.

Eureka Mining, Smelting & Power Co. *v.* Lively, (Wash.) 110 Pac., 425. Aug., 1910.

Assumption of Risk and Contributory Negligence

An employee in a mine does not assume the risk of injury arising from the employer's violation of the statutory duty, and a miner has the right to wait a reasonable time for the owner or operator of the mine to repair an insufficient covering on the cage before being chargeable with contributory negligence where he is injured by an object falling down the shaft, unless the hazard was so great that a reasonably prudent person would not expose himself to the danger; and whether the miner was guilty of contributory negligence in such a case is a question for the jury on all the evidence.

Poli *v.* Numa Block Coal Co., (Iowa) 127 Northwestern, 1105. Oct. 1910.

Duty of Mining Company to Provide Safe Place—Covering over Cage

It is the duty of a mining company to provide a safe place of work for its miners, and this duty cannot be delegated or left to the discretion of the servants. The statute of Iowa provides that proper covers be provided overhead on mine cages to protect the employees and others who may be on the cage or in the shaft from injury from the falling of objects from above. A mining company or an operator of a mine cannot escape liability for its failure to provide such a safe place by leaving the operation of the mine without responsible care and oversight.

Poli *v.* Numa Block Coal Co., (Iowa) 127 Northwestern, 1105. Oct. 1910.

Construction of Gas and Oil Lease

A gas and oil lease provided for the payment of $100 yearly for each and every well drilled and from which gas was transported or used off the land and that the lessee should deliver to the lessor one-sixth of all the oil produced and saved from the premises. The lessee entered upon the premises and drilled six wells which produced both gas and oil. In an action on the lease and contract to recover the rentals it was held that the lessee could not fraudulently refuse to transport the gas from the premises for the sole purpose of defrauding the lessor out of the rentals, and that the payment of the royalty for the oil did not prevent a recovery of the royalty for the gas.

Pittsburg-Columbia Oil & Gas Co. *v.* Broyles, (Ind.) 91 Northeastern, 574. May 1910.

Personal

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

S. F. SHAW is at Porcupine.

H. F. BAIN has gone to Juneau.

C. J. LONDON is in San Francisco.

KARL HOFMANN is in San Francisco.

E. B. KIRBY has been in San Francisco.

CHARLES JANIN has returned from Colorado.

GEORGE E. FARISH is in British Columbia.

E. A. HAGGOTT, of Los Angeles, is in Mohave county, Arizona.

NED J. CHURCHILL is superintendent of the Tennessee mine, at Chloride, Arizona.

R. D. GEORGE is recovering rapidly and will go East to recuperate, when able to travel.

JOHN DERN, president of the American Mining Congress, was in Washington June 15.

W. C. HALL, of Fairbanks, Alaska, is in San Francisco, and will go north again this month.

H. M. WILSON, chief engineer of the Bureau of Mines, visited Birmingham, Alabama, recently.

FREDERICK G. CLAPP has returned to Pittsburg, after a trip of six weeks in the Mexican oilfields.

MARION S. MACCARTHY, of Alamos, Mexico, was in San Francisco and has gone to Victoria, B. C.

WILL C. RUSSELL has returned from New York to Colorado, for the Rawley Mining Co., at Bonanza.

E. H. Messiter is now vice-president of the Electric Weighing Co. at 180 13th avenue, New York.

ROBERT E. CRANSTON has gone to Grangeville, Idaho, to examine the placers at Big Bend on the Salmon river.

JOSEPH A. HOLMES attended the annual meeting of the American Society of Mechanical Engineers, Pittsburg, June 2 and 3.

HOWARD POILLON has been appointed manager of the mines and oxide plant at Cutter, New Mexico, for the Vanadium Mines Company.

W. H. STORMS has returned to Berkeley from Tuolumne county, California, where he has been engaged in geological work on the Jumper and Golden Rule mines.

Obituary

NATHANIEL W. LORD, head of the Department of Mining and Metallurgy at Ohio State University, and former consulting chemist of the Technologic branch of the United States Geological Survey, died of heart failure on May 23. He was for years identified not only with the work in mining at Ohio University, but also with the fuel-testing work there, in which he set new standards for such work. A brilliant man of science, a powerful teacher, and a good citizen, he leaves many to mourn his going on before.

THE death of Dr. ROBERT W. ELLS, geologist of the Canadian Geological Survey, occurred at Ottawa on May 23, as the result of a paralytic stroke. He was born at Cornwallis, N. S., in 1845, and graduated from McGill University in 1872 with first-class honors. He joined the staff of the Survey in that year and spent the rest of his life in its service. Dr. Ells was a Fellow of the Royal Society of Canada, and of the American Geological Society, and represented the province of Ontario on the Corporation of Mc Gill University. He published numerous reports on the geology and mineral resources of the provinces, as well as many papers for scientific societies. He was best known in recent years for his work in connection with the problem of utilizing the oil shales of eastern Canada, his memoir published in 1910 being the standard authority on that subject.

Market Reports

LOCAL METAL PRICES.

San Francisco, June 22.

Antimony	12—12¾c	Quicksilver (flask)	46.50
Electrolytic Copper	14—15¼c	Tin	47—48¾c
